Part 2: Analytics ... 1283

CHAPTER 11: Overview of RapidResponse analytics ... 1285
Core analytics ... 1285
Analytic modifiers ... 1287
Analytic compatibility and limitations ... 1291
CHAPTER 12: Calendars and date calculations ... 1295
Calendar tables ... 1295
Dates and time spans ... 1296
RapidResponse date values ... 1297
Date constants ... 1303
RunDate and DataDate ... 1303
Date calculation rules ... 1304
Calendar date display values ... 1306
CHAPTER 13: Lead time calculations ... 1307
Lead time dates ... 1307
Lead time elements ... 1308
Lead time calendars ... 1317
Inclusive and cumulative lead time ... 1323
Lead time rounding ... 1327
Lead time overrides from scheduled receipts ... 1328
CHAPTER 14: Material Requirements Planning calculations ... 1331
Netting basics ... 1331
Rescheduling supplies ... 1335
Explosion ... 1337
Explosion and order BOMs ... 1342
Planned orders ... 1343
Planning time fence ... 1344
Planned orders with MRP rules ... 1351
Planned orders with order point ... 1351
Inventory levels and planned orders ... 1358

Order Policy and planned orders ... 1358
Planned order lot sizing ... 1358
Days of Supply calculations ... 1362
Shortage calculations ... 1375
Limitations on the number of planned orders ... 1376
Start date calculation for planned orders ... 1376
Spreading planned orders with Takt Time ... 1376
Part source selection ... 1377
Examples of part source selection ... 1382
Part sources for scheduled receipts ... 1389
Phantom processing ... 1390
Yield ... 1391
Supply ... 1396
Demand ... 1397
Allocation data ... 1399
Safety stock ... 1400
Safety stock policy configuration ... 1401
Basic safety stock rules ... 1402
Safety stock calculations ... 1402
Analytic limitations with safety stock ... 1418
Ignoring unsatisfied demands ... 1420
Recursive data ... 1423
CHAPTER 15: Master Production Scheduling calculations ... 1425
Demand types ... 1425
Forecast spreading ... 1426
Forecast consumption ... 1431
MPS configuration ... 1442
Dependent forecast on scheduled receipts ... 1446
Forecast consumption by pool/customer ... 1447
Available to promise ... 1449
CHAPTER 16: Inventory turns calculations ... 1451
CHAPTER 17: Capable-to-Promise calculations ... 1453
Capable-to-promise tables ... 1454
Sample data used in CTP examples ... 1454
Available date calculations ... 1456
Gating part calculations ... 1457
Gating constraint calculations ... 1458
Late supply calculations ... 1458
VMI parts and supply demand allocation records ... 1458
Allocation of supply to demand ... 1458
Allocating limited supplies ... 1464
Improve on-time quantity by reallocating late supply ... 1471
Incremental availability calculations ... 1476
Incremental availability basics ... 1476
Constraints and incremental availability ... 1478
Controlling incremental availability calculations ... 1479
Best practices for incremental availability results ... 1484
Analytic limitations with incremental availability ... 1487
CTP data examples ... 1488

CHAPTER 18: Full-level pegging calculations **1493**
Full-level pegging tables 1493
Full-level pegging data example 1496
Full-level pegging through allocations 1499
Full-level pegging reporting horizon 1501
CHAPTER 19: Cost of goods sold calculations **1503**
Allocated scheduled receipts 1503
Unallocated scheduled receipts 1505
Calculating PCOGS material costs 1505
Calculating PCOGS labor costs 1508
Calculating PCOGS overhead costs 1509
CHAPTER 20: Cost roll-up calculations **1511**
Calculating CR material costs 1511
Calculating CR labor costs 1512
Calculating CR overhead costs 1513
CHAPTER 21: Capacity Requirements Planning (CRP) calculations **1515**
Capacity Requirements Planning data model 1515
About Capacity Requirements Planning calculations 1519
Scheduled receipts and planned orders 1520
Routings 1521
Operations and sequences 1522
Operation phases and durations 1523
Sequencing and parallel operations 1524
Operation lot splitting 1526
Ongoing operations 1526
Overlapping operations 1527
Aligning dependent requirements to operations 1531
Operations and supply lead time 1532
Work centers and capacity 1534
Operation loads 1536
WorkCenter loads 1538
Limitations on other analytics with CRP 1540
CHAPTER 22: Kanban calculations **1541**
Enabling kanban calculations 1541
Impacts on netting calculations 1542
Impacts on capable-to-promise calculations 1542
Limitations on other analytics with kanban 1543
CHAPTER 23: Interchangeable parts **1545**
Setting up interchangeable parts 1545
Analytics with interchangeable parts 1549
CHAPTER 24: Global part substitution **1551**
Setting up part substitution 1551
Limit substitute usage to excess supply 1558
Enable customer-specific part substitution 1560
Part substitution calculations 1562
Limitations on other analytics 1562
CHAPTER 25: BOM level part substitution **1565**
Substitute BOM configuration 1566
Define substitutable components 1567
Specify usage of substitute supply 1569

Define planned order generation ... 1571
Specify date effectivity ... 1574
Substituting groups of components ... 1574
Substitutable allocations ... 1576
Limitations on other analytics ... 1578
CHAPTER 26: Co-products and by-products ... 1581
Co-product and by-product basics ... 1581
Co-product and by-product data model ... 1582
Configuring co-products and by-products ... 1583
Co-product and by-product calculations ... 1596
Limitations on other analytics ... 1598
CHAPTER 27: Material expiration ... 1601
Setting up expiry data ... 1601
Expiry calculations ... 1609
Calculating the earliest expiry date on a demand ... 1611
Calculating the expiry date on supplies ... 1616
Calculating the expiring quantity on a supply ... 1624
Unsourceable demands due to material expiry ... 1625
Limitations on other analytics ... 1626
CHAPTER 28: Constraint Analysis calculations ... 1629
Understanding constraint ... 1629
Constraint Analysis data model tables ... 1630
Constraints on part sources ... 1631
Families and multi-level constraints ... 1633
Constraint Analysis process overview ... 1635
Planning with fixed and variable constraints ... 1642
Planning with multiple constraints ... 1643
Planning with multi-level constraints ... 1644
Reporting constraint loads ... 1645
Constraint Analysis control settings ... 1651
ProcessingRule ... 1652
Rescheduling rules ... 1653
ConstraintDateRule ... 1654
OrderPriority rules ... 1657
SchedulePriority ... 1659
SplitLateSupply ... 1662
AllowLatePlan ... 1663
FillSchedule ... 1665
AvailableDateLimit ... 1666
SchedulingRule ... 1667
PrePlanRule ... 1676
FairShareAllocation ... 1679
Respecting order policy rules ... 1684
Control settings and calculated fields in Netting ... 1685
CHAPTER 29: Production Planning calculations ... 1691
Production Planning data model ... 1691
Managing production wheel constraint ... 1693
Handling unused constraints and unsatisfied supplies ... 1694
Changeover in production ... 1697
Part sources in production wheels ... 1698

Scheduled receipts and planned orders ... 1699
Production wheel durations and cycle lengths ... 1699
Production recurrence ... 1702
Limitations with other analytics ... 1703
CHAPTER 30: Campaign planning ... 1707
Campaign planning data model ... 1707
Configuring campaigns ... 1708
Campaign planning calculations ... 1710
Limitations on other analytics ... 1715
CHAPTER 31: Distribution planning ... 1717
Configuring distribution planning for pushing ... 1717
Distribution planning calculations ... 1718
Forward-bucketed fair share ... 1726
Limitations on other analytics ... 1730
CHAPTER 32: Multi-site calculations ... 1731
Sites ... 1731
Transfer part sources ... 1731
Transfer scheduled receipts ... 1734
Using address data to support maps ... 1735
CHAPTER 33: Model and Unit Effectivity calculations ... 1737
Model effectivity ... 1737
Unit effectivity ... 1738
Explosion based on effectivity ... 1739
Cumulative lead time ... 1741
Capacity load calculations ... 1742
CHAPTER 34: Inventory Pooling calculations ... 1745
Understanding pools ... 1745
Pool netting ... 1745
Pool, model and unit netting factors ... 1746
Pool, model and unit netting ... 1748
Pools and part sources ... 1750
CHAPTER 35: Alternate BOM calculations ... 1759
Alternate BOM basics ... 1759
Effects on Netting calculations ... 1761
Best practices for using alternate BOMs ... 1762
Default BOMAlternate record ... 1764
CHAPTER 36: Order priority calculations ... 1765
Order priority tables and fields ... 1765
Priority calculations ... 1767
Effective priority ... 1767
Effective transaction sequence ... 1769
Priorities on dependent demands ... 1770
Prioritized demand order ... 1771
CTP supply allotments ... 1771
Safety stock and priority adjustments ... 1773
Priority and safety stock holds in CTP ... 1780
Priorities on scheduled receipts ... 1788
Priorities on planned orders ... 1790
Constraint planning and usage ... 1794
Prioritized demand examples ... 1795

Prioritized supply examples ... 1799
CHAPTER 37: Two-date planning ... 1803
Two-date planning configuration ... 1803
Provide request date on independent demands ... 1804
Enable two-date planning by priority level ... 1805
Ensure supply sources can plan to request dates ... 1806
Apply safety lead time at request date (optional) ... 1807
Two-date planning calculations ... 1810
Limitations on other analytics ... 1814
CHAPTER 38: Attribute-based planning ... 1817
Supported analytics ... 1817
Configuring attributes ... 1818
Configure control table settings ... 1818
Create attributes ... 1820
Create and define attribute fields ... 1821
Define attribute rules ... 1825
Attribute calculations ... 1827
Supply allotment by attribute ... 1827
Forecast consumption by attribute ... 1830
Forecast adjustment by attribute ... 1831
Attribute-based planning examples ... 1832
CHAPTER 39: Feature BOMs ... 1845
Setting up Feature BOMs ... 1845
Feature BOM calculations ... 1848
Limitations on other analytics ... 1850
CHAPTER 40: Allotment overrides ... 1853
Setting up allotment overrides ... 1853
Allotment override calculations ... 1856
Allotment override examples ... 1857
CHAPTER 41: Multi-level search logic ... 1863
Multi-level search configuration ... 1863
Enabling multi-level search logic ... 1864
Multi-level part source effectivity ... 1865
Partial planning ... 1866
Fairshare of material and constraints ... 1868
Including material cost as a selection criteria ... 1869
Reducing short-term excess inventory ... 1870
Limiting the number of part sources evaluated ... 1870
Other control settings to consider ... 1871
Pre-defined resources supporting MLS ... 1873
Multi-sourcing ... 1876
Multi-level part source selection criteria ... 1877
Substitution ... 1909
Non-blocking allocations ... 1916
Limitations on other analytics ... 1926
MLS infrastructure changes (optional and limited release) ... 1929
CHAPTER 42: Inventory planning and optimization ... 1935
Single and multi-echelon basics ... 1936
Safety stock item data model ... 1937
Single-echelon data model ... 1938

Multi-echelon data model ... 1942
Safety stock item configuration ... 1946
Define IP&O parameters ... 1947
Provide historical data for safety stock calculations ... 1947
Configure control settings for safety stock calculations ... 1948
Set safety stock bounds (optional) ... 1959
Configure multi-echelon lead time parameters (optional) ... 1960
Define safety stock item mappings (optional) ... 1962
Define single-echelon average demand profiles (optional) ... 1962
Use forecast error pooling for safety stock (optional) ... 1963
Single-echelon safety stock calculations ... 1968
Safety stock item outlier processing ... 1983
Multi-echelon safety stock calculations ... 1989
Create multi-echelon families ... 1990
Calculate inventory holding costs for MEIO ... 1996
Determine demand and supply parameters for MEIO ... 1999
Recommend safety stock ... 2005
Apply safety stock bounds in MEIO ... 2010
Automated safety stock updates ... 2012
Comparing single-echelon settings and multi-echelon settings ... 2014
CHAPTER 43: Statistical forecasting ... 2019
Statistical forecasting tables ... 2019
Statistical forecast configuration ... 2020
Statistical forecasting operations ... 2030
Statistical forecasting models ... 2031
Univariate time series forecasting models ... 2032
Multiple Linear Regression forecasting models ... 2042
Multiple linear regression tables ... 2044
Multiple linear regression calculations ... 2047
Additional forecasting options ... 2052
Data characteristics ... 2059
Error measures ... 2060
CHAPTER 43: Consensus forecast ... 2069
Consensus forecast data model ... 2070
Consensus forecast calculations ... 2072
Consensus forecast category weights ... 2073
Consensus forecast adjustments and overrides ... 2079
CHAPTER 44: Forecast disaggregation ... 2083
General disaggregation data model ... 2083
General disaggregation rates ... 2087
Configuring general forecast disaggregation ... 2088
Statistical disaggregation data model ... 2098
Statistical disaggregation rates ... 2102
Configuring statistical forecast disaggregation ... 2103
CHAPTER 45: Event Management ... 2109
Action types for event phases ... 2110
Event Management and the RapidResponse data model — Input tables ... 2112
A process for adjusting forecast values using Event Management ... 2114
Using curves to adjust the forecast ... 2116
Event Management and the RapidResponse data model — calculated tables ... 2120

Date bucketing and disaggregation of event phase forecast adjustments 2124
Adjusting the forecast by negative amounts 2133
CHAPTER 46: Self-Healing Supply Chain 2135
Self-Healing Supply Chain model 2136
Lead time data model 2137
Yield data model 2139
Self-Healing Supply Chain data flow 2141
Self-Healing Supply Chain calculations 2146
Self-Healing Supply Chain configuration 2153
CHAPTER 47: Project management calculations 2161
Integrated project management data model 2161
Task scheduling 2167
Task durations 2176
Resource efficiency 2181
Resource availability and exceptions 2183
Leveling task resources 2186
Project costs 2188
Penalties 2191
Bonuses 2196
CHAPTER 48: Configuring analytic calculations using global settings 2203
Calculating TimeUnit records 2203
Limiting the number of planned orders 2204
Configuring buckets for Inventory Analysis tables 2205
Defining a periods of coverage calendar 2206
Configuring AbsolutePrePlanLimit usage 2206
Enabling automatic maintenance of TransactionSequence values 2207
Configuring task finish date calculations 2208
Defining the And operator for feature rules 2208
CHAPTER 49: Configuring analytic calculations using workbook parameters 2209
Include inactive IndependentDemands in the Activity and CTPActivity tables 2210
Include inactive ScheduledReceipts in the Activity and CTPActivity tables 2211
Include inactive OnHand in the Activity and CTPActivity tables 2212
Duplicate supplies and demands in the Activity and CTPActivity tables 2212
Merge PartSources and BOMs in FlatBillDown and FlatBillUp calculations 2215
Include non-primary part sources in FlatBillDown and FlatBillUp calculations 2217
Include substitute BOM components in FlatBillDown and FlatBillUp calculations 2218
Include global substitutes and their components in FlatBillDown calculations 2219
Explode BOMs for "NoOrders" parts in FlatBillDown calculations 2221
Apply a parameter date to FlatBillDown calculations 2222
Limiting FlatBillDown and FlatBillUp calculations by model 2224
Specify workbook-specific Inventory Analysis buckets 2225
Specify a reporting horizon for WhereConsumed records 2227
Specify a reporting horizon for WhereConsumedForForecast records 2229
Specify a reporting horizon for WhereConsumedForSupply records 2230
Specify a reporting horizon for WhereConsumedToHighVolumeOrder records 2232
Enabling feature-based queries on IndependentDemandByFeature records 2234
Specifying the number of levels used in WhereConsumedForSupply calculations 2235
Calculate general disaggregation rates by forecast category 2236

Part 3: Configuring resource calculations **2237**

CHAPTER 50: Kanban Manager calculations **2239**
Kanban Manager tables 2239
ShopKanban calculations 2240
SourceKanban calculations 2242
Configuring Kanban Manager calculations 2244
CHAPTER 51: Multi-enterprise resources **2249**
Configuring the Multi-Enterprise Inventory workbook 2249
Configuring the Multi-Enterprise Management workbook 2250
Configuring multi-enterprise data 2251
CHAPTER 52: Data validation resources **2253**
Configuring outsourced manufacturing validation 2253
Configuring demand management validation 2254
CHAPTER 53: Clear to Build resources **2257**
Configuring Clear to Build calculations 2257
Configuring orders in the Clear to Build workbook 2258

Part 4: Analytic and data model change summary **2259**

CHAPTER 54: Data model calculations after upgrading **2261**
CHAPTER 55: Analytic and data model changes in 2019 ..... **2263**

CHAPTER 1: Welcome

This guide provides reference information about the RapidResponse data model. This guide can be used by users involved with integrating data into RapidResponse and workbook authors (report writers).

All tables and fields are described in this guide. Information is also provided about RapidResponse analytics and calculations.

In this chapter, you'll learn more about:

What's in this Guide **113**
About Kinaxis **114**

Note: For information about changes made to recent versions of the RapidResponse data model, see "Part 4: Analytic and data model change summary" on page 2259.

What's in this Guide

This guide is divided into four parts each of which contains numerous chapters. The following is a brief overview of the information contained in each part:

- **Part I: Table and field reference**—provides and overview of the RapidResponse data model, and contains reference for each table and field it contains. Individual chapters describe the input, calculated, and control tables in the data model.
- **Part II: Analytics and calculations**—provides an overview of the standard and optional analytics in RapidResponse, as well as detailed information on configuring and understanding the calculations produced by each analytic. Individual chapters exists for most of the main analytics, or calculation types, in RapidResponse.
- **Part III: Configuring resource calculations**—provides an overview of and describes how to configure the calculations performed by certain RapidResponse resources.
- **Part IV: Analytic and data Model Change Summary**—provides an overview of changes made to the data model in recent versions of RapidResponse. For each new version, all new tables and fields are listed, along with descriptions of new analytics and potential changes in calculated output.

What you need to know

This guide assumes that you are familiar with RapidResponse. This guide also assumes that you are familiar with manufacturing concepts such as Material Requirements Planning (MRP) and your enterprise data sources.

About Kinaxis

Kinaxis® delivers cloud-based S&OP and supply chain applications for discrete manufacturers and brand owners with complex supply chain networks and volatile business environments.

Leaders across multiple industry verticals, including A&D, Automotive, High Tech, Industrial and Life Sciences rely on RapidResponse® applications to create a foundation for concurrent planning, continuous performance monitoring, and coordinated responses to plan variances across multiple areas of the business. All founded on a single product, RapidResponse's configurable applications encompass a full spectrum of supply chain processes, including such functions as S&OP, supply planning, capacity planning, demand planning, inventory management, MPS, and order fulfillment.

As a result, Kinaxis customers have replaced disparate planning and performance management tools and are realizing significant operations performance breakthroughs in planning cycles, supply chain response times and decision accuracy. From a single product, customers are able to easily model varying supply chain conditions to make both long-term and real-time demand and supply balancing decisions quickly, collaboratively, and in line with the shared business objectives of multiple stakeholders.

For more information, visit www.kinaxis.com or the Kinaxis Knowledge Network at http://knowledge.kinaxis.com/.

CHAPTER 2: Accessing help and documentation

Determining which help system or guide to use **116**
Documentation conventions **118**
Finding the content you need in HTML help **118**
Your feedback **119**
Help embedded in resources **120**
Other ways to learn about RapidResponse **125**
Customer Support **126**

The RapidResponse documentation set includes several different help systems and guides, each dealing with a different area of knowledge. Help for individual resources, such as workbooks is also available.

In addition to the RapidResponse documentation, you can access a variety of other resources to help you learn about the capabilities and features in RapidResponse. These include an online community where you can view how-to videos and find advice, a mailing list that you can use to keep up to date on supply chain news and upcoming events, and instructor-led training courses.

Accessing RapidResponse help systems and guides

You can access RapidResponse help systems and guides two ways:

- Access documentation directly from the Help menu in RapidResponse.
- For links to all of the available help systems and guides, see "Determining which help system or guide to use" on page 116.

Account permissions and the contents of your Help menu

The list of options you see when you click the Help menu in RapidResponse depends on the permissions associated with your RapidResponse account. The more permissions you have in RapidResponse, the more options you see on the menu. For example, resource authors have more permission than general users.

Links to documentation that you are less likely to need, based on your permissions, are not shown on the Help menu. For example, users without administrator permissions do not see Administration Help.

Documentation formats

Most RapidResponse documentation resources are available as both HTML help systems and PDF documents. Some documentation is only available in PDF format.

HTML help systems are optimized for viewing in a web browser. While it is possible to print individual topics from HTML help, you will get better results if you print the topic or topics from the equivalent PDF guide.

PDF guides are optimized for printing. They can be viewed and printed using Adobe Reader®. You can download Adobe Reader from the Adobe site at www.adobe.com.

Accessing help for RapidResponse resources

Help is often available in the RapidResponse application window for individual resources of the following types:

- Dashboards and widgets
- Worksheets and workbooks
- Scorecards
- Forms
- Scripts
- Responsibility definitions

For more information, see "Help embedded in resources" on page 120.

Determining which help system or guide to use

The RapidResponse documentation set includes several help systems and guides, each dealing with a different area of knowledge. The following table summarizes the available documentation, some of which you can access from the Help menu in RapidResponse.

Title	Description
RapidResponse User Guide	This guide provides RapidResponse users with basic reference and procedural information. It covers topics such as viewing data, modifying data as part of simulation, solving business problems, and customizing the user interface.
RapidResponse User Guide (Mobile Client)	This guide provides information on how to view and edit data in the Mobile Client.
RapidResponse Applications Guide	Practical ways to use RapidResponse and the applications that can be deployed to support business processes and make decisions. It also includes instructions aimed at RapidResponse administrators that outline how to install and configure applications.

Title	Description
RapidResponse Fundamental Concepts Guide	RapidResponse product overview, which includes key capabilities and the deployment methodology.
RapidResponse Resource Authoring Guide	This guide provides information on creating and managing resources, such as dashboards, workbooks, and filters. Detailed information about RapidResponse Query language is also included.
RapidResponse Analytic and Data Model Guide	Description of the RapidResponse data model and associated analytics. All tables and fields in the data model are listed and described. This guide also notes changes to the data model corresponding to the RapidResponse release.
Data model posters	A series of posters illustrating the structure of tables and fields in RapidResponse, and the relationships between fields. For more information, see "Data Model Posters" on page 117.
RapidResponse Administration Guide	Information for administrators, covering installation, upgrades, maintenance, system settings, and user administration.
RapidResponse Scripting Guide	Information about building custom applications using scripting language objects, functions, and methods to automate some RapidResponse processes.
RapidResponse Web Services Guide	Information on using RapidResponse Web services to create users, resources, and Web service client programs.
RapidResponse Data Integration Guide	Information about integrating enterprise data sources with RapidResponse, including mapping data from source tables and fields, customizing the RapidResponse database, extracting data from enterprise sources, performing data updates to bring new and updated data into RapidResponse, moving data between RapidResponse instances, and moving data changes between RapidResponse and business partners in real-time.
Global Help	If you are not sure which help system contains the information you need, you can search for it in this help system, which includes information from all of the other help systems.
Release summary	The latest release summary outlines all of the changes that have been made in RapidResponse 1908, including new features and defect resolutions in service updates. Release summaries can be found in the Kinaxis Knowledge Network in the Documentation Center.
Custom Help	Your company might have also created custom help specific to your RapidResponse implementation.

The permissions associated with your RapidResponse account affect the list of guides that you can access from the Help menu. For more information, see "Account permissions and the contents of your Help menu" on page 115.

Data Model Posters

Users who have permission to create resources such as workbooks and dashboards have access to the following posters on their RapidResponse Help menus:

- *RapidResponse Data Model for Import poster*—displays the relationship between the tables and fields used in the RapidResponse data import process.

- *RapidResponse Calculated Data Model poster*—displays the relationship between the main RapidResponse database calculated tables and fields. Calculated fields in the RapidResponse data model input tables are also displayed.
- *RapidResponse Sales & Operations Planning poster* —displays the relationship between the tables used to support the Sales & Operations Planning application.
- *RapidResponse Inventory Planning and Optimization poster* —displays the relationship between the tables used to support Inventory Planning and Optimization application.
- *RapidResponse Integrated Project Management poster* —displays the relationship between the tables used to support Integrated Project Management application.
- *RapidResponse Historical Supply poster* and *RapidResponse Historical Demand poster*—displays the relationship between all tables (input, control, and calculated) that are used to store historical supply data and historical demand data, respectively.

Documentation conventions

To help you quickly locate and interpret information, Kinaxis guides use conventions noted in the following table.

	Convention	Description
	bold	Bold is used for user-interface elements in procedures. For example: On the **File** menu, click **New**.
	italic	Italic is used when citing other documents. For example: For more information, see the *RapidResponse Administration Guide*.
	`Courier New`	Courier New is used for programming examples and text that is entered in Microsoft Windows Command Prompt window or command lines.
	Caution:	Identifies a caution message (critical information).
	Note:	Identifies a note.
	Tip:	Identifies a tip.

If you are using a Mac OS, procedures that use the Windows CTRL key should be replaced with the Mac OS Command key.

Finding the content you need in HTML help

You can find information in any RapidResponse HTML help system by searching or by browsing in the contents or the index.

Searching the help

You can find the information you require by entering a term in the Search box. You can also refine your search by using AND or OR to search for a combination of words, and you can put quotation marks around your search word or phrase to search for that exact phrasing only. For example, "sort" would return any topics with the word "sort", but not the words "sorted" or "sorting".

Search for content

- Type a search term in the search bar and then click .

Note: If you do not want the words you searched for highlighted in the help topic, click **Remove Highlights** .

Tip: If the browser window is small, the search bar might not be displayed. To see a search bar click or enlarge the window.

Browsing the contents and the index

You can also find information by browsing in either of these panes:

- **Contents**—Browse through the topics in the table of contents.
- **Index**—Find a topic through the index. Scroll through the index or type a word or phrase in the Search Index box to find an index entry.

Tip: If the browser window is small, the Contents and Index panes might not be displayed. To see them, click or enlarge the window.

Your feedback

Kinaxis Inc. takes great pride in developing user-friendly applications and we hope that our documentation resources ensure a high level of usability. We welcome your feedback about the help topics you access.

If you have comments or suggestions about Kinaxis documentation or training materials, you can email them to learning-techsupport@kinaxis.com.

Help embedded in resources

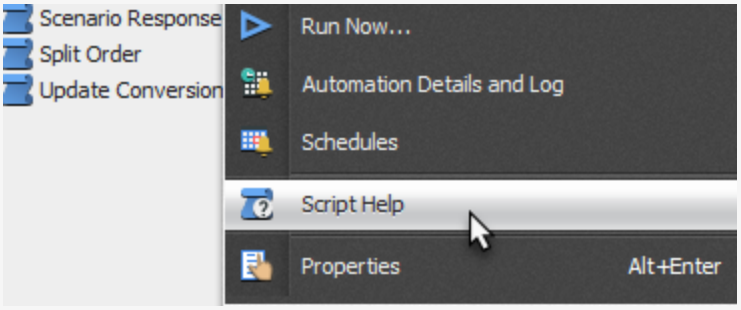
Many openable RapidResponse resources have help embedded within the resource. The form the help takes depends on the type of resource.

When help is available for a resource, you can view it from the open resource. You can also view the help for some types of resources from the Explorer, without having to open the resource first. These resources include workbooks, scorecards, widgets, forms, and scripts. Viewing resource help from the Explorer can help you to determine whether a resource is the right one to use, without having to wait for it to load.

View resource help without opening the resource

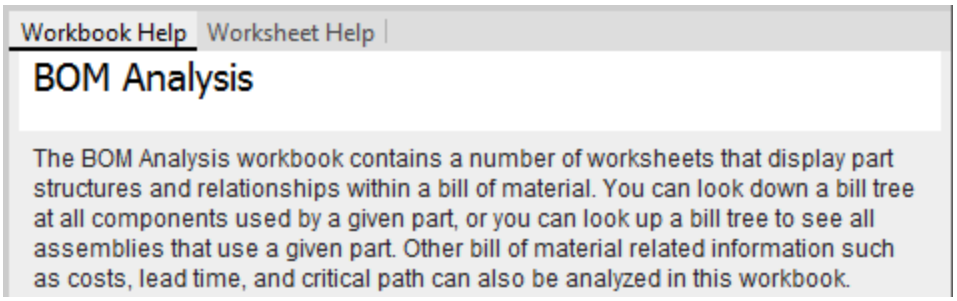
- In the **Explorer**, select a resource and then click ⓘ beside the name of the resource.

Tip: You can also view resource help from the Explorer by right-clicking the name of the resource and then selecting the Help option for the resource from the menu. For example, to view help for a script, click Script Help.



View and print worksheet and workbook help

RapidResponse worksheets can include a help page that is displayed in a pane on the right-hand side of the worksheet. Workbooks might also include a help page, in which case, the help pane includes two tabs: Workbook Help and Worksheet Help.



Show or hide the help pane

- On the **Help** menu, click **Show Workbook/Worksheet Help**.

Note: This command is not available for workbooks that do not have workbook help or help for at least one worksheet defined.

Tip: You can also show or hide the help pane by clicking **Show Workbook/Worksheet Help** on the toolbar.

Print the worksheet or workbook help

You can print the worksheet or workbook help when the help pane is displayed.

1. On the **File** menu, click **Print**.
2. Click **Worksheet help** or **Workbook Help**, and then click **OK**.

Note: The worksheet and workbook help are printed as they appear in the help pane. Widen the help pane before printing to maximize the amount of information printed on a page.

Tip: You can also print the worksheet help by right-clicking in the help pane, and then clicking **Print**.

View and print scorecard help

Each scorecard in RapidResponse includes a help page that is displayed in a pane on the right-hand side of the scorecard. You can show and hide the scorecard help pane.

- On the **Help** menu, click **Show Scorecard Help**.

Note: This command is available only for scorecards that have help defined.

Tip: You can also show or hide the scorecard help pane by clicking **Show Scorecard Help** on the toolbar.

Print the scorecard help

You can print the scorecard help when it is displayed.

1. On the **File** menu, click **Print**.
2. Click **Scorecard help**, and then click **OK**.

Note: The scorecard help is printed as it appears in the help pane. Widen the worksheet help pane before printing to maximize the amount of information printed on a page.

Tip: You can also print the scorecard help by right-clicking in the help pane, and then clicking **Print**.

View dashboard and widget help

Dashboard help is often available for a dashboard as a whole, and you might also be able to view help for individual widgets.

Dashboard help

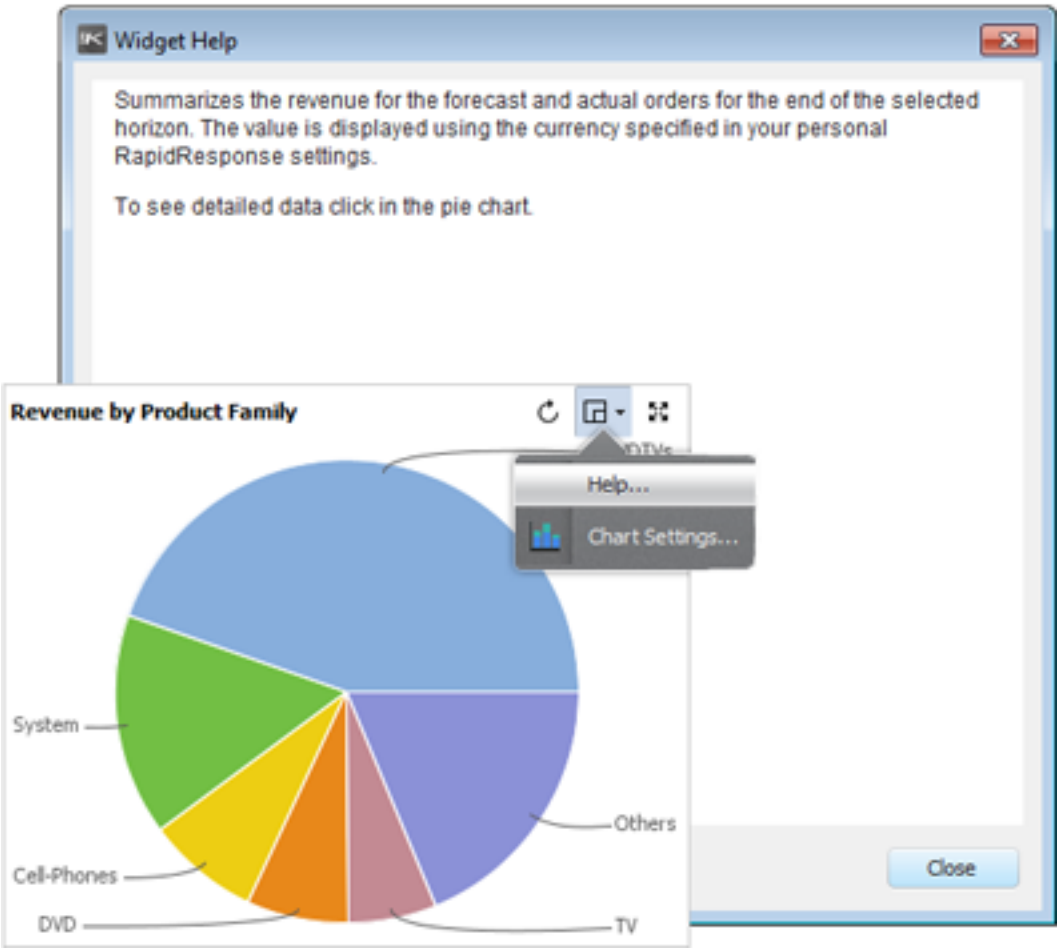
Some dashboards might have an Information tab with a text widget that shows dashboard help. Dashboard help contains information about how the dashboard is intended to be used, and can include links to related resources, websites, or help videos.

Widget help

Most widgets on dashboards that are supplied with RapidResponse have widget help, and some custom widgets might also include help. Widget help typically describes the metrics displayed in a widget, and might include links to other resources such as workbooks and websites. You can access help for widgets directly from the widget controls on a widget on your dashboard.

View widget help

- On a widget title bar, click **Actions**, and then click **Help**.
  The widget help displays in a dialog box.

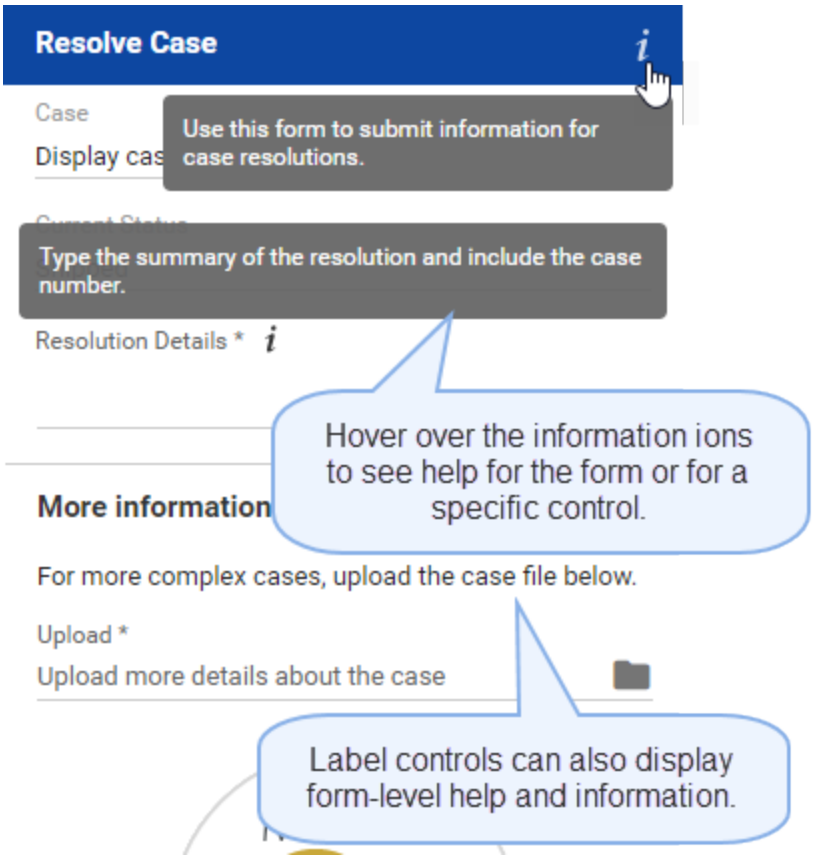


View form help

Forms can display three types of help: contextual help directly on the form, form pop-up help, and field pop-up help.

Both contextual help and form pop-up help might describe the purpose of the form, how to use it, or what happens when the form is run. Contextual help displays right on the form. Form pop-up displays when you hover over the information icon at the top right corner of the form.

Individual fields on a form might also display help specific to the field, such as what types of values it accepts.



View pop-up help for a form

1. On the form, point to the information icon in the upper right corner of the form
   Form help displays below the form title bar.
2. Point away from the information icon to close the help.

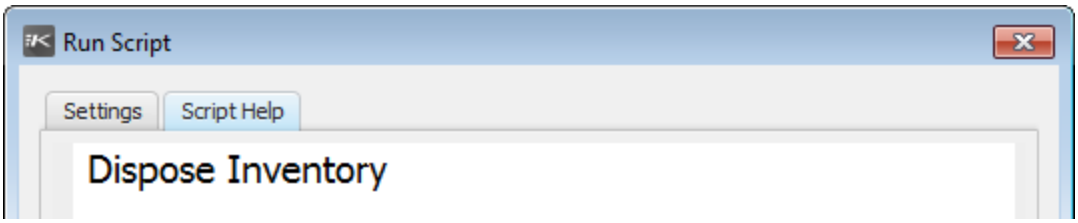
Note: Only forms with help display the information icon in the upper corner of the form.

View pop-up help for a field

1. Point to the field you want to view help for.
   Only fields with help display next to the field title
2. Point to the information icon on the field.
   Help for the field displays above or below the field.
3. Point away from information icon to close the help.

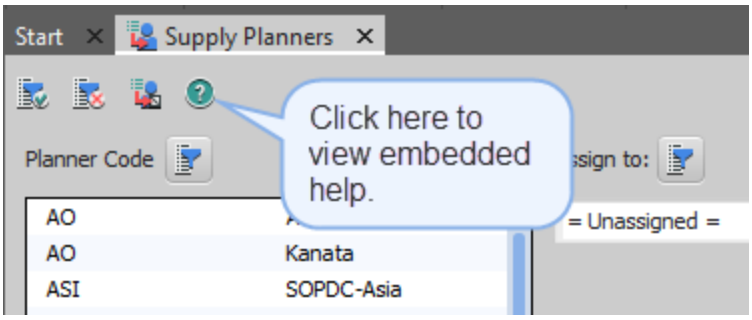
View script help

Some scripts might have embedded help. If a script has embedded help, a Script Help tab is shown when you run the script.



View help for a responsibility definition

You might be able to access embedded help for an open responsibility definition. If help is available, a Responsibility Help button is available near the top left of the tab.



Resources without embedded help

Some types of resources, such as filters, cannot have embedded help, and not every resource that could have embedded help does have embedded help. Resource authors decide whether or not to include help when they create new resources that can have embedded help.

Sometimes, the information needed to use that resource might be available elsewhere. For example, if you access a dashboard by opening it from a task flow, the information you need to understand the purpose of the dashboard might be included in the task flow. Another example is a custom resource created for your company, which might be documented in company procedures that are maintained outside of RapidResponse.

Other ways to learn about RapidResponse

In addition to the RapidResponse documentation set, there are several other ways to learn about RapidResponse.

Kinaxis Knowledge Network

Visit the Kinaxis Knowledge Network at knowledge.kinaxis.com to access features including:

- Upgrade Center—Learn what's new in each version of RapidResponse.
- Training videos—Familiarize yourself with the basic capabilities of RapidResponse by taking an introductory course, delivered as a series of short videos. You can also view videos on some more advanced topics.
- Discussion Forums—Discuss RapidResponse with other users.
- Blogs—Learn how others are using RapidResponse and solving supply chain problems.

Some content is only available after you create a Kinaxis Knowledge Network user account and sign in.

News mailing list

Subscribe to the mailing list to stay up-to-date on news and upcoming supply chain events, such as Kinexions, the annual Kinaxis training and user conference. You can find the subscription form at http://info.kinaxis.com/customer-subscription-page.

Training courses

Kinaxis offers instructor-led courses and self-paced online training courses to help you develop in-depth RapidResponse knowledge. Instructor-led courses are usually delivered online in a virtual classroom, but on-site instruction can also be arranged. To see a list of available courses, visit https://www2.kinaxis.com/rapidresponse-training/courses.cfm.

Customer Support

The Kinaxis Customer Support team understands demand and supply chain planning, monitoring and response, and is experienced in applying RapidResponse to real-world business scenarios. Areas of expertise include:

- RapidResponse functionality
- Data extraction and mapping issues
- Technical software compatibility
- Coordination of integration
- Product implementation

If you are a key support contact, you can submit support cases. To submit a support case, log into the Kinaxis Knowledge Network. You can also contact Kinaxis Customer Support by phoning 1-866-463-7877 or by sending a message to support@kinaxis.com.

Kinaxis Knowledge Network

The Kinaxis Knowledge Network is the place to find knowledge about RapidResponse. In one site, you can:

- Search all knowledge about RapidResponse, including product documentation, knowledge base articles, and threaded discussions about common questions.
- Review your company's Customer Support requests (and, if you are a key support contact, create new Support requests).
- Engage with a community of RapidResponse experts in the Discussion Groups.

Go to https://knowledge.kinaxis.com and log in today. You can also access the Kinaxis Knowledge Network from RapidResponse by clicking **Kinaxis Knowledge Network** on the **Help** menu.

Part 1: Table and field reference

- RapidResponse database
- Introduction to the RapidResponse data model
- Optional applications and tables
- Input tables
- Control tables
- Calculated tables
- Notes tables
- Referenced system tables

CHAPTER 3: RapidResponse database

The following chapters in this guide provide reference information about all tables in the RapidResponse data model. Each of these tables is associated with a particular namespace and classified as belonging to one of several distinct types. Each field contained in a table is also classified as belonging to a specific field type. As well, the data contained in each field belongs to a specific type. This chapter introduces the concept of namespaces as well as each of the table, field, and data types described in this guide.

In this chapter, you'll learn about:

Namespaces **131**
Table types **133**
Historical tables **134**
Vector data **138**
Field types **140**
Data types **143**
Invalid characters in data **145**
Accuracy of calculated results with long numbers **146**
Data Model dialog box **147**

Namespaces

The RapidResponse database includes namespace support. Namespaces are abstract containers used to identify and give context to groupings of related data model tables. This allows for the modeling of multiple data model schemas within RapidResponse, and provides a means to identify and distinguish between tables that have the same name but different purposes.

By default, the RapidResponse data model tables described in this guide belong to one of the following namespaces:

- **Core**—holds a small group of foundational tables that are used to support calculations in both standard RapidResponse tables and any custom tables added for your organization. This namespace includes tables that hold site, calendar, and currency information.
- **Mfg**—holds tables containing demand, supply, and part/item information used to support Supply Chain Management (SCM) and Sales and Operations Planning (S&OP) resources in RapidResponse.
- **MLService**—holds tables and fields used to support Machine Learning services in RapidResponse.
- **ProcOrch**—holds tables containing information about process instances and supports process orchestration in RapidResponse.

- **ProjMgmt**—holds tables containing project, tasks, and resource information used to support Integrated Project Management resources in RapidResponse.
- **Solutions**—holds tables and fields used to support RapidResponse applications such as Master Production Scheduling and Order Fulfillment.
- **SupCollab**—holds fields used to support data automation for supplier collaboration processes and to communicate supplier and buyer commitments.
- **Validation**—holds tables and fields used to perform input validation from an SAP data source.

If you are using a data integration server with the Integration Toolkit, additional namespaces are available. A namespace is created for each source system that data is brought in for.

Each namespace created specifically for the data integration server has an origin of 'Data Integration', and should not be migrated to the planning server. Data in these namespaces is automatically managed by the Integration Toolkit and cannot be modified. For more information, see the *RapidResponse Data Integration Guide*.

Because all of the namespaces included with RapidResponse are read-only, new tables and fields cannot be defined within them. However, your organization can create new namespaces for this purpose.

For example, you might create multiple namespaces to hold and identify groups of custom tables being added in different functional areas of your business, or you might create a single generic namespace to hold all of your company's custom tables.

Similarly, namespaces can also be used to hold custom fields added to tables in other namespaces (typically, tables in standard, non-editable RapidResponse namespaces). For example, if you wanted to add a field named Margin to the standard IndependentDemand table which is contained in the Mfg namespace, that field would need to be defined in a custom namespace. This ensures that if a field named Margin were added to the standard IndependentDemand table in a subsequent RapidResponse release, it would be distinguishable from your Margin field by namespace.

When working with and selecting tables in the RapidResponse interface, the table name is sometimes displayed along with its namespace. This typically occurs when the namespace is required to distinguish between identically named tables. In such cases, you might see table names presented in the format *TableName (Namespace)*; for example, *Customer(Mfg)* and *Customer(Xyz)*.

Similarly, in the reference section of this guide, the description of each table and its fields identifies the table's namespace in the format `TableName(namespace)`; for example `Task(ProjMgmt) fields`.

Also when defining RapidResponse resources such as workbooks, fields included in expressions sometimes need to be specified along with their namespace in the format `Namespace::Fieldname` (for example, `Mfg::Suppliers)`. This is required when using fields defined in a namespace other than the one the table itself belongs to, and when there are multiple fields of the same name defined on a given table.

Similarly, in the reference section of this guide, fields on a table that reference tables in namespaces other than the one the table itself is contained in are noted in the format `Namespace::TableName` (for example, `Core::Site`).

Notes:

- If your RapidResponse installation has ever upgraded from a Version earlier than 11.0, a User namespace is also available and contains all custom tables and fields added prior to upgrading to Version 11.0. These custom tables and fields all begin with a prefix of "U_".

- For information about working with namespaces when authoring RapidResponse resources, see the *RapidResponse Resource Authoring Guide*. For information about creating and maintaining namespaces, see the *RapidResponse Data Integration Guide*.
- If you integrate data using the Integration Toolkit, namespaces specific to the data integration server are also available. These include namespaces that are typically named after your enterprise data sources and contain tables that represent data you are mapping from the enterprise data source. These namespaces exist only on the data integration server and should not be migrated to the planning server.

Table types

The following discusses the table types in the RapidResponse data model.

Table 3.1: RapidResponse table types

Type	Description
Input	Contain the fields that hold data imported from your enterprise data source. These fields are used as input by RapidResponse when performing its algorithmic calculations, and are editable. However, some input tables also contain calculated fields which are part of the record structure, but are generated by RapidResponse calculations and are not editable. An example of an input table is the **ScheduledReceipt** table. This table contains any supply for a single part that has an assigned due date (for example, work orders and purchased orders). For more information, see "Input tables" on page 171.
Calculated	Store data produced by RapidResponse calculations. Calculated tables can be classified as either Planning or Consolidated. A planning calculated table is populated with the result of calculations performed by RapidResponse. For example, the PlannedOrder table stores recommended supply orders generated by RapidResponse calculations. A consolidated planning table is made up of a union of multiple tables or the presentation of a multi-stage summarization and filtering process. For example, the Activity table consolidates data from supply, demand, and on hand tables into a single place. For more information, see "Calculated tables" on page 937.
Control	Control tables contain the rules and values that determines how RapidResponse interprets the data stored in input tables, and hence the results shown in calculated tables. The data in control tables is set up during a RapidResponse implementation to represent the types of data, codes, and processing rules of the enterprise data source. These rules are modifiable on a per scenario basis which allows for scenarios that analyze the impact of a global policy change (for example, a change in safety stock rules). For more information, see "Control tables" on page 669.
Notes	Used to store the data entered in Notes fields associated with the EngineeringChange, IndependentDemand, ScheduledReceipt, SupplyAllocation, SupplyOrder, and Task tables. Notes tables are automatically created when a custom Notes field is added to a table. For more information, see "Notes tables" on page 1269.
System	System tables hold information used internally by RapidResponse, such as user information, system settings, or any other information that is not directly used in calculations or imported from an enterprise system. Most system workbooks are based on system tables. You cannot create or modify worksheets based on system tables except for presentation attributes such as column headers, sorting, grouping, worksheet help, and fonts. Only system tables and fields that are referenced from other tables are described in this document. For more information, see "Referenced system tables" on page 1275.

Historical tables

The RapidResponse data model includes tables for storing and analyzing historical data. Historical tables in RapidResponse are available for both historical demand data and historical supply data, as well as to archive key performance indicator data values and currency conversion rates.

Editing data in historical input tables

For all general RapidResponse users, historical input tables are read-only and cannot be edited. This is because historical tables are intended strictly for analysis purposes and not for simulations.

However, as a RapidResponse administrator, you have the ability to edit historical data to reflect other data changes in RapidResponse. You might need to move data from input demand or supply tables to historical demand or supply tables. For example, certain forecasts imported into the IndependentDemand table might be edited by RapidResponse users and, when these edited forecast values are accepted, the new values should be copied to the historical demand tables. Also, bucketed demands for components may need to be copied from the Demand tables to the historical demand tables in order to be used in waterfall reports. Similarly, bucketed open and planned supply needs to be copied from the Supply table to the historical supply tables in order to be used in waterfall reports.

Data updates and historical data

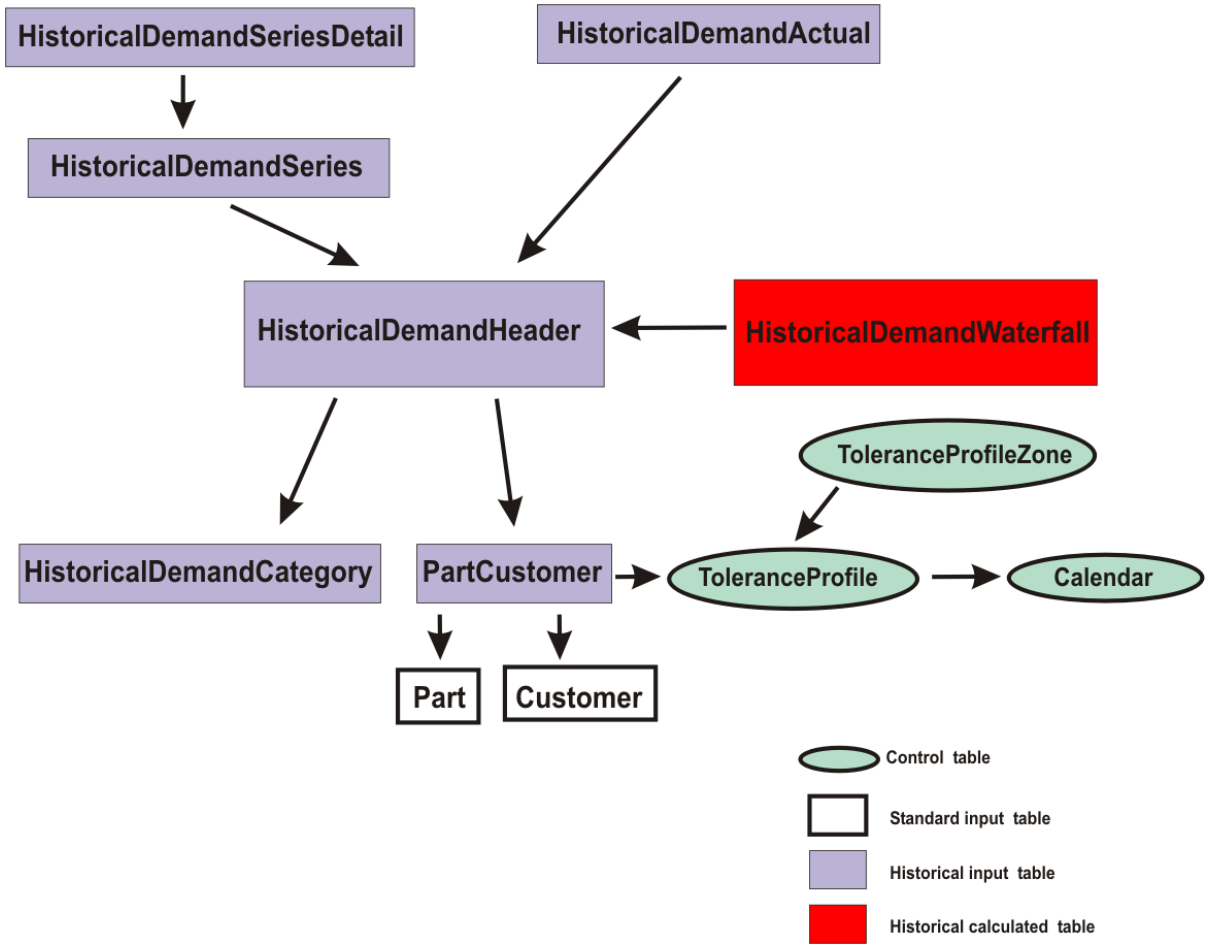
Historical data supplied in data updates can insert records into the historical tables. However, depending on your company's historical data requirements, you can configure the historical tables to also modify or delete historical records, similarly to other RapidResponse tables. To modify these tables, you must be a data or system administrator with permission to modify data integrations. For more information, see the *RapidResponse Data Integration Guide*.

During a data update, only new data should be provided for historical tables as the existing data is not deleted during the update. Instead, a RapidResponse command can be used to delete data from the historical tables as required. As well, the initial bulk import of historical data must be performed as part of a data update operation using the DataUpdate command. For detailed information about managing data in historical tables, see "Managing historical data" in the *RapidResponse Data Integration Guide*.

Historical demand tables

Historical demand data includes details of historical forecasts as well as actual shipments to customers or distribution centers. As shown in the following illustration, data must be provided for two main input tables; **HistoricalDemandSeriesDetail** and **HistoricalDemandActual**.

Figure 3.1 Historical demand tables

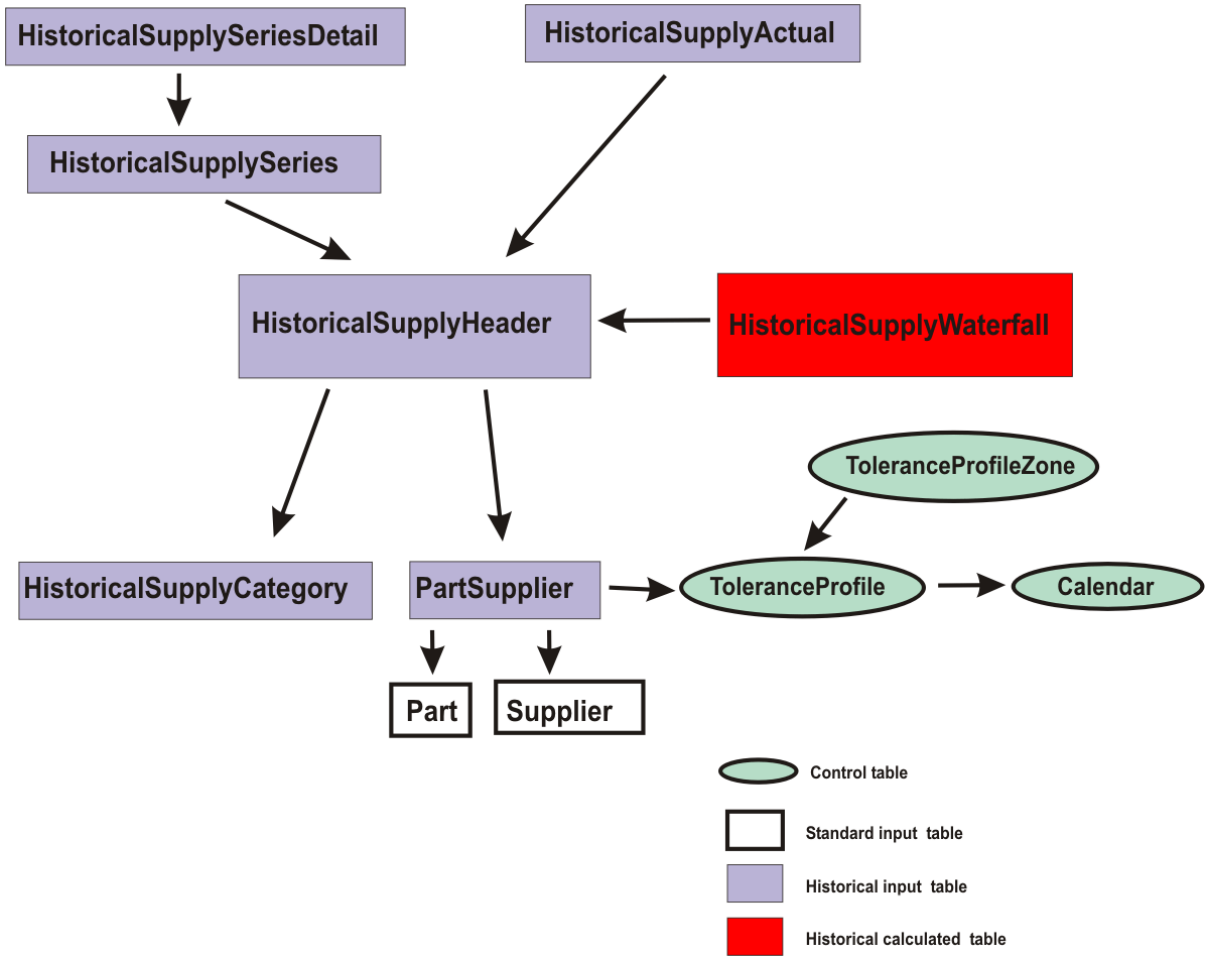


The **HistoricalDemandSeriesDetail** table holds the details of each historical demand series (forecast data), and **HistoricalDemandActual** holds details of actual shipments of parts (from fulfillment sites to customer, manufacturing sites to distribution centers, and so on). RapidResponse can then auto-create the necessary references to other related input tables. As well, a RapidResponse analytic populates the calculated **HistoricalDemandWaterfall** table. This table consolidates the historical forecast and actual demand data into a single table useful for analyzing forecast accuracy and creating waterfall reports.

Historical supply tables

Historical supply data includes details of historical supply series as well as actual orders placed with suppliers. As shown in the following illustration, data must be provided for two main input tables; **HistoricalSupplySeriesDetail** and **HistoricalSupplyActual**.

Figure 3.2 Historical supply tables



The **HistoricalSupplySeriesDetail** table holds the details of each historical supply series, and **HistoricalSupplyActual** holds details of actual orders placed with suppliers. RapidResponse can then auto-create the necessary references to other related input tables. As well, a RapidResponse analytic populates the calculated **HistoricalSupplyWaterfall** table. This table consolidates the historical supply series and actual supply data into a single table useful for creating waterfall reports.

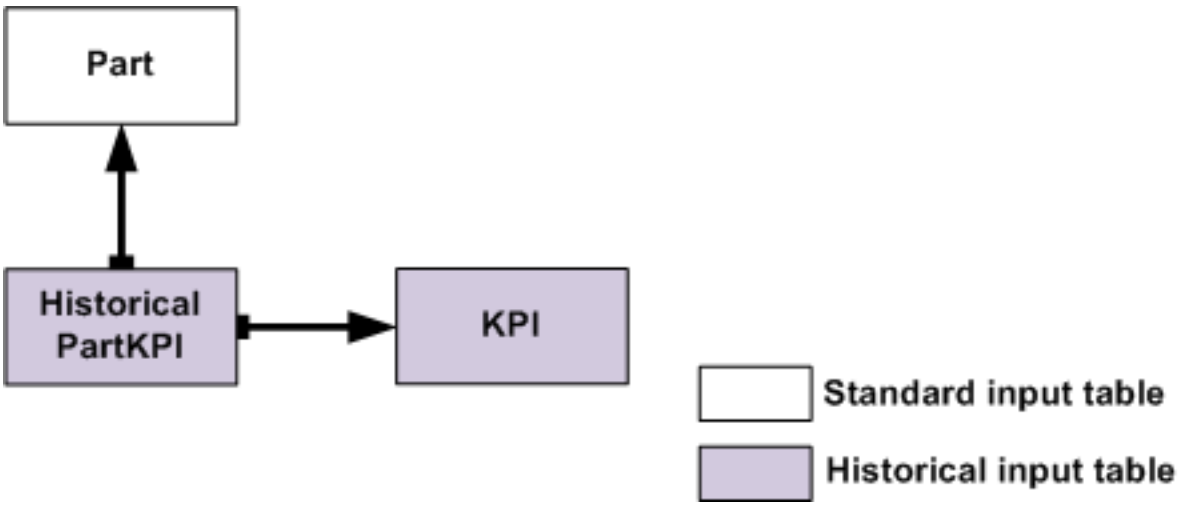
Historical KPI tables

Key performance indicators (KPI), such as orders at risk and revenue opportunities, are calculated and can be reported.

In RapidResponse, a series of automatic data modifications are configured during integration to periodically create data in the HistoricalPartKPI and KPI tables.

The **HistoricalPartKPI** table contains part-based historical key performance indicator data. Each record in this table identifies a part, key performance indicator, and the quantity value associated with that part and KPI combination on a specific date. The **KPI** table identifies each key performance indicator, and has its records automatically created based on values added to the HistoricalPartKPI table.

Figure 3.3 Historial KPI tables

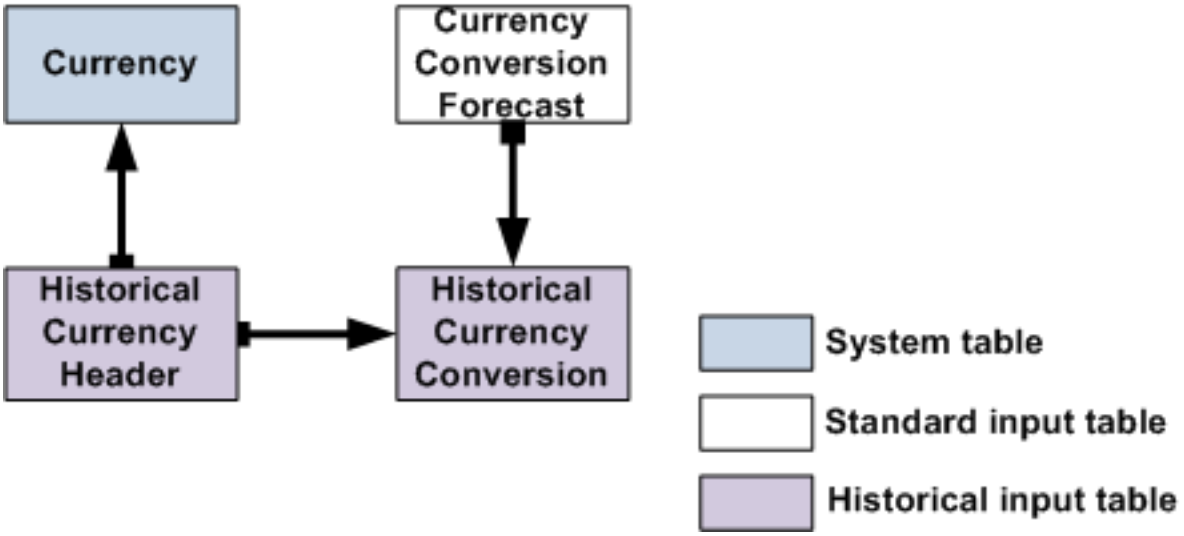


Historical currency tables

Currency conversions are represented using a conversion rate, which is multiplied or divided by a value to convert between the currency and the system's base currency. Conversion rates change over time, and in some cases you might want to use a rate calculated from a previous period. For example, you might want to report currency values for orders over the past six months.

The **HistoricalCurrencyHeader** table contains date-based currency data. Each record in this table identifies a date that historical conversion rates are available for. The **HistoricalCurrencyConversion** table contains the conversion rates for each currency as of the specified historical date. The conversion rates are taken from the **CurrencyConversionForecast** table.

Figure 3.4 Historical currency tables diagram



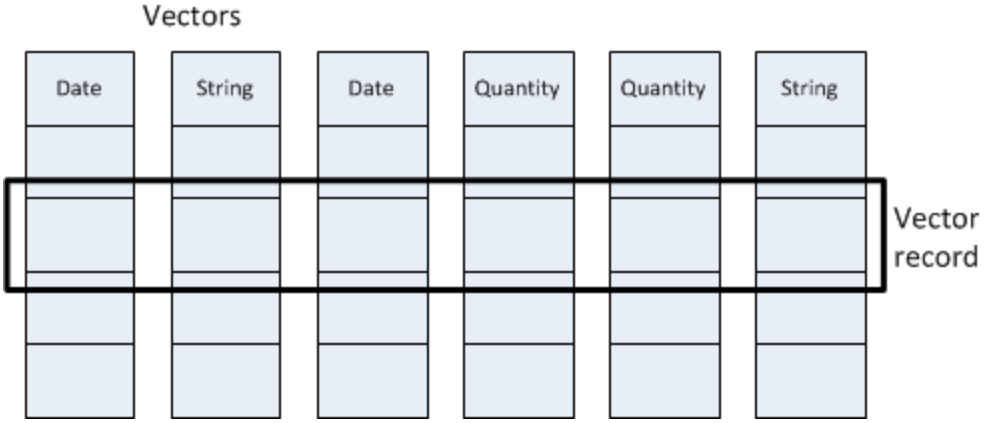
Vector data

Some input tables contain vector data, which consists of arrays of values. Each vector can contain any number of values, each with the same data type. For example, a vector of Date values can contain any number of calendar dates. Vectors are stored in memory and can be reused multiple times. If similar values are needed in multiple tables, using a vector can reduce memory consumption by storing the data one time in vectors and accessing the vectors from each table that requires them.

Vectors are assembled into a set of records under a shared owning record. These records can contain up to 96 fields. Any operation performed on the records within the vector set are performed as a single operation, regardless of how many records are in the set. For example, if an operation modifies 50 records in the vector set, all 50 modifications are performed at one time. A similar operation on a standard table would perform all 50 modifications separately.

The vectors in a set are always the same length. The set of vector values at the same position in each vector in the set represent a vector record.

Figure 3.5 Vector records



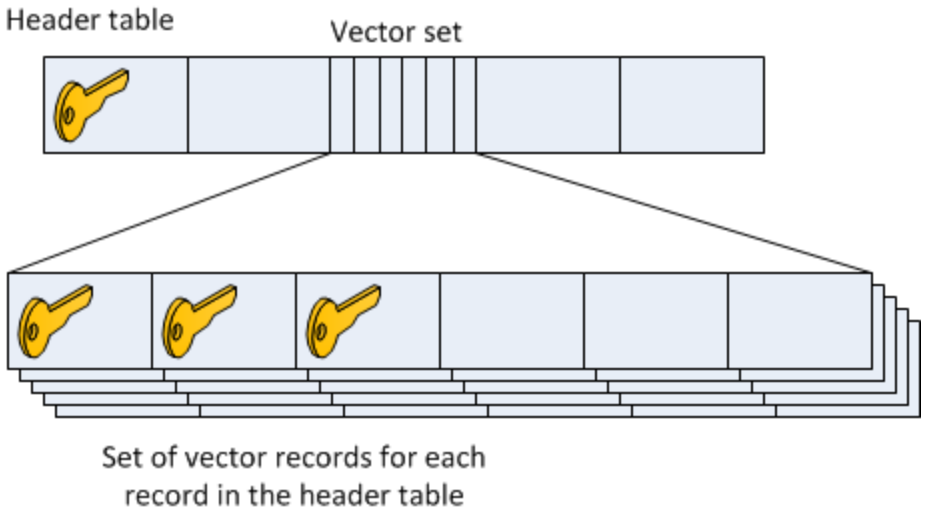
Vector records exist only in the context of the vector set field, which is represented as a field on the table that owns the vector set. Each record in the owning table has its own set of vector records, which can be constructed from the same individual vectors as required.

Vector sets are represented as tables that contain the individual vectors that comprise the required data as fields. These fields must uniquely identify values within the vector. Vectors have the same key field requirements as input tables, however, the vector set contains a reference to the owning table, called the owning reference, which is also used as a key field. For more information about key fields, see "Key fields" on page 141.

On the owning table, the vector set field contains an identifier that defines the vectors that are used in the set. This identifier consumes the same memory as a standard field, and is the only value stored in the table for the entire vector set, regardless of how many values are present in the vectors. For more information about the memory requirements for fields, see "Data types" on page 143.

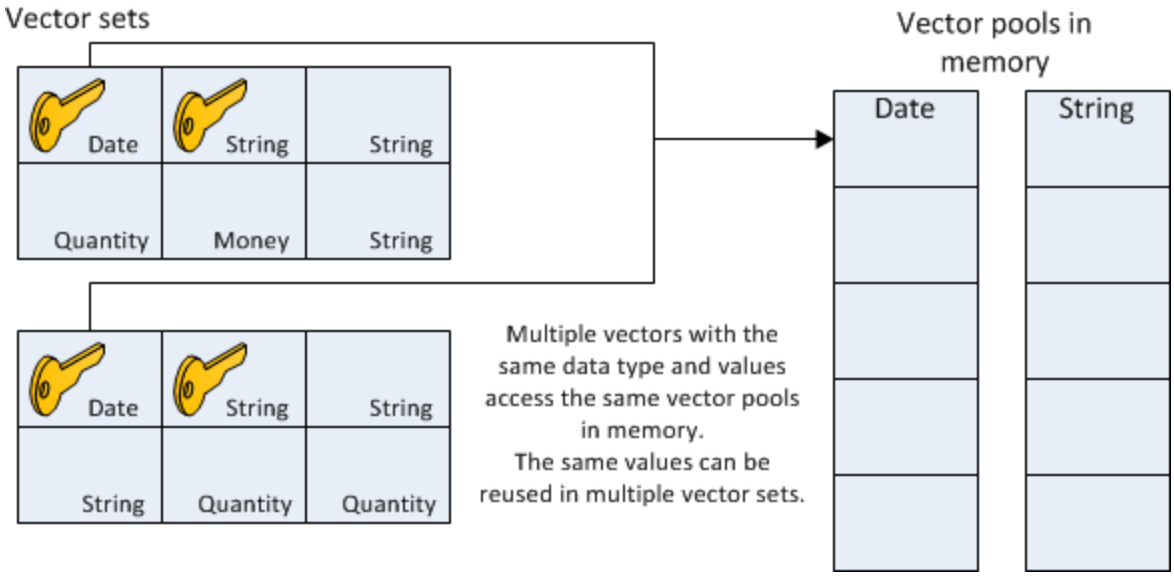
A vector set is typically used to optimize or replace a header and detail table structure where many detail records are created for each header record. The vector set contains the detailed records for each record in the header table.

Figure 3.6 Relationship between a vector set and its owning table



The groupings of vector key fields are used to sort the records in the vector set, and affect how values are read from the vector pools. For example, for a vector set that contains a Date field and a Type field as its keys, the vector set is sorted by date and then by type. The values that line up with those date and type values in each vector are retrieved from the vector pools, and can be reused for other vector sets that use the same key fields.

Figure 3.7 Reusing vector pool values



Because the vector set's key values are stored in memory, they can be accessed by any vector set with the same groupings of key fields. This improves performance and reduces memory consumption because the key values are not stored as records in the vector table. This requires less memory than would be needed to store the equivalent number of detailed records in each individual vector set.

Vector data is brought in with other data during a data update, and each vector that is loaded is available to be reused by another vector set. For example, a Date vector can be populated with monthly values, and then that vector can used in any other vector set that requires the monthly values. If data in a vector set is modified, the vector is replaced with the new values. If values are inserted into the vector set, they are inserted where required in the sort order of the vector sets.

Field types

Each field in a RapidResponse table belongs to one of the following field types:

Table 3.2: RapidResponse field types

Type	Description
Base field	A base field represents an individual piece of information contained in a table. For example, in the ScheduledReceipt table, Due Date is a base field as it represents the specific due date associated with the order. Each base field contains either data imported from an enterprise data source or data generated by RapidResponse analytic calculation.
Reference field	A reference field is a link to another field in a table with a one-to-one relationship. For example, on the ScheduledReceipt table, Part is a reference field as each scheduled receipt is for exactly one part. A reference field can typically only contain values stored in the referenced table. For example, each scheduled receipt must be for a part already defined in the Part table. However, a small number of reference fields in the standard RapidResponse data are nullable, and all custom reference fields (unless designated as part of their table's key fields) can be configured to be nullable. For more information, see "Nullable references" on page 142.

Table 3.2: RapidResponse field types

Type	Description
Set field	A set field is a link between two tables where there is a one-to-many relationship. It represents a set of summary records on the other table. For example, on the Part table, ScheduledReceipts is a set field as each part can have more than one scheduled receipt. As a result, each part has a set of records containing summarized information about all its receipts.
Vector set field	A vector set field represents a vector table, which contains the series of detailed data for each record in a header table. Vector fields are accessed similarly to set fields.

Key fields

Some RapidResponse fields also act as key fields. The key fields for a table consist of one or more fields that form a unique combination of values in a table. Any combination of base or reference fields can be used as keys, and a table can contain up to eight key fields. Fields of the following data types can be used as key fields:

- String
- Reference
- Date
- Time
- DateTime
- Boolean
- Integer

For more information about these data types, see "Data types" on page 143.

The key fields for vector sets also include a reference to the table that owns the vector, which is one of the table's key fields. This field cannot be removed and must be a key field.

Only tables where record uniqueness is required have key fields. For example, the Name and Site fields make up the keys of the Part table as each part name and site combination in the RapidResponse data model must be unique. Conversely, the Capacity table does not have key fields, and records added to this table are not required to be unique.

A small number of tables in the RapidResponse data model that do not contain key fields by default can be configured with key fields. These tables are:

- Allocation
- BillOfMaterial
- OnHand
- Operation

These tables, and the standard tables that contain vector data, are the only standard RapidResponse tables you can add or modify key fields in.

Nullable references

Reference fields are used to point to actual values stored in other tables. Many reference fields on input tables are mandatory and must point to a valid value in the referenced table. Reference fields that must point to a valid value on another table include all reference fields that make up part of the table's key, most control table references, and a small number of other input table references that point to required data.

For example, on the **ScheduledReceipt** table, the reference to the **SupplyOrder** is required as it is part of the table's key, the reference to the **SupplyStatus** table is required as it contains settings used in determining how each receipt is processed by RapidResponse analytics, and the reference to the **Part** table is required to identify the actual part the receipt is for.

However, many other input reference fields that do not contain mandatory data can be left empty or "Null". For example, on the **ScheduledReceipt** table the reference to the Shipment table can be left Null as not all receipts will be part of a shipment, and the AllotmentOverride reference can be left null as allotment overrides are generally only used on an exception basis.

When a reference field is set as nullable, that field value can be left empty (Null) and no defaults are applied if a reference value is provided. Nullable reference fields can be utilized in cases where a given reference field is not always expected to be populated. If a nullable reference field is followed from a record where no reference value was provided, only an empty reference is returned and any base fields on the referenced record return their data type's default value (for example, 0.0 for Quantity, Undefined for Date, and so on).

Nullable references also differ from standard reference fields in how they handle record deletions in a referenced table. If a reference field is not nullable and a given record is deleted from the referenced table, then all records that reference that deleted value are also deleted. This known as a cascading deletion. Nullable reference fields can, optionally, be configured so that instead of their records being deleted when a referenced value is deleted, the reference is set to Null instead.

Notes:

- All nullable reference fields in standard input tables are identified as such in the Input tables chapter of this guide. This is noted after the name of the referenced table in the field description. For example, **Referenced table**: BuyerCode (Nullable).
- For information about designating custom reference fields as nullable, or to find out which of your company's custom reference fields are nullable, see the *RapidResponse Data Integration Guide* or talk to your RapidResponse administrator.
- If writing query expressions that use nullable reference fields, you might need to adjust your logic to account for the possibility of a null reference. For this purpose, the IsNull function can be used to detect records on which a reference is actually null as described in the *RapidResponse Resource Authoring Guide*.
- Reference fields in a vector table or reference fields that are used as key fields cannot be made nullable.

Nullable references in versions prior to 10.1

The concept of a nullable reference was introduced in RapidResponse version 10.1. In subsequent releases, many new non-key reference fields have been designated as nullable.

Additionally in Version 10.1., a number of existing reference fields were set as Nullable. However, for users upgrading from versions prior to 10.1., they were designated as non-nullable during the upgrade process.

Thus, the reference fields listed in the following table are generally nullable in all new installations of RapidResponse from version 10.1 and later. However, for installations that have ever been upgraded from a version earlier than 10.1, these references are not nullable.

Table 3.3: Nullable references in new RapidResponse installations 10.1 and later (only)

Table	Namespace	Reference Field	Referenced Table
Allocation	Mfg	Shop	Shop
BillOfMaterial	Mfg	EffectiveInEC	EngineeringChange
BillOfMaterial	Mfg	EffectiveOutEC	EngineeringChange
BillOfMaterial	Mfg	Shop	Shop
BillOfMaterial	Mfg	SubstituteGroup	SubstituteGroup
Customer	Mfg	CustomerGroup	CustomerGroup
IndependentDemand	Mfg	ShipSet	ShipSet
PartCustomer	Mfg	ToleranceProfile	ToleranceProfile
PartSupplier	Mfg	ToleranceProfile	ToleranceProfile
ScheduledReceipt	Mfg	Shipment	Shipment
Shipment	Mfg	Carrier	Carrier
Supplier	Mfg	SupplierGroup	SupplierGroup
WorkCenter	Mfg	Department	Department

Data types

Each field in a RapidResponse table supports a particular data type. The data type determines the type of data a field can contain, and subsequently the types of queries that can be performed on it. The following table outlines the data types supported in the RapidResponse data model.

Table 3.4: Data types

Type	Description	Memory allocation
Boolean	Either a **Y** (Yes or True) or **N** (No or False) value. This data type is treated similarly to the String data type in RapidResponse, except that it accepts only two possible values and consumes less memory per record.	2 bytes
Date	A date value. The valid date range is from January 2, 1970 to December 31, 2037. Undefined, Future, and Past values are also permitted, and represent dates outside the valid range.	4 bytes
DateTime	A date and time value with the same range as the Date type. A time zone value can be added; if not, RapidResponse uses the client's local time zone. The value can be Past, Future, or Undefined.	4 bytes

Table 3.4: Data types

Type	Description	Memory allocation
Integer	Whole number with an optional preceding minus sign. Valid range is -2,147,483,648 to 2,147,483,647.	4 bytes
Money	A real number (whole and decimal fraction numbers) representing a monetary value. All Money values have an associated currency, and can be converted to other currencies or represented as a raw (unconverted) value. Any money value, consisting of a number and an associated currency. The valid range of values is -1.79769313486231**E**308 to 1.79769313486231**E**308. Values with more than 308 decimal places (**E**-308) are interpreted as zero values. This data type uses a double-precision floating number. You can also use exponential notation to express this number.	8 bytes
Note	Stores notes data. If you add a Note field to a custom table, RapidResponse creates a corresponding Notes table (the Notes table takes the name of the custom table and adds the suffix _**Notes**). Each time a note is added to the Note field in the custom table, a notes record is created and stored in the corresponding Notes table. For more information, see "Notes tables" on page 1269.	4 bytes for each record in a RapidResponse table that has the Note field. Per note instance: 20 bytes + size of UserId who created the note + size of Note text.
Quantity	A real number (whole and decimal fraction numbers) with an optional preceding minus sign. The valid range of values is -1.79769313486231**E**308 to 1.79769313486231**E**308. Values with more than 308 decimal places (**E**-308) are interpreted as zero values. This data type is also known as a double-precision floating number. You can also use exponential notation to express this number.	8 bytes
QuantitySingle	A real number (whole and decimal fraction numbers) with an optional preceding minus sign. The valid range of values is -3.402823**E**38 to 3.402823**E**38. Values with more than 45 decimal places (**E**-45) are interpreted as zero values. This data type is also known as a single-precision floating number. You can also use exponential notation to express this number. **Note:** This data type can only be used by custom fields.	4 bytes
Reference	A reference to custom or standard RapidResponse table. The reference typically must contain a value for each of the referenced table's key fields.	8 bytes
String	A series of alphanumeric characters.	8 bytes or greater depending on the length of the string.
Time	A time value entered in the format shown above. It can be an explicit time using the 24-hour format, hh:mm:ss.	4 bytes
Vector Set	A vector table that contains the date-phased detail records for a header record. Each unique value in the vector's key fields is stored once within the vector records and referenced from all other records where that value is used.	8 bytes

Notes:

- Non-printing control characters, such as line breaks or null characters, are not supported in RapidResponse. For specific examples of data types that are not supported, see the *RapidResponse Administration Guide*.
- For information about the rules and syntax required when including the different data types in queries, see the *RapidResponse Resource Authoring Guide*..
- Some string fields described in this guide are also marked as Enum. These are fields which contain or return values from a list of predefined strings. For example, many of the fields containing processing options in control tables are identified as Enum.

Invalid characters in data

The table below lists the control and non-printable characters that RapidResponse reads as invalid. Avoid the use of these characters to prevent data errors.

Character	ASCII Character	Unicode Value	Description
0, Nul, \0, ^@	U+0000	U+2400	Null
SOH, ^A	U+0001	U+2401	Start of Header
STX, ^B	U+0002	U+2402	Start of text
ETX, ^C	U+0003	U+2403	End of text
EOT, ^D	U+0004	U+2404	End of transmission
ENQ, ^E	U+0005	U+2405	Enquiry
ACK, ^F	U+0006	U+2406	Acknowledge
BEL, \a, ^G	U+0007	U+2407	Bell
BS, \b, ^H	U+0008	U+2408	Backspace
FF, \f, ^L	U+000C	U+240C	Form feed
SO, ^N	U+000E	U+240E	Shift out
SI, ^O	U+000F	U+2401	Shift in
SUB, EOF, ^Z	U+001A	U+241A	Control-Z
ESC, \e, GCC only, ^[	U+001B	U+241B	ESC/Escape
SP, SUB	U+0020	U+2420	Space
ƀ	U+180B	U+2422	Blank
NL, \n	U+0085	U+2424	Next line

Accuracy of calculated results with long numbers

RapidResponse stores and computes Quantity data (whole and decimal fraction numbers) as floating-point numbers. Simply put, "floating point" refers to the number of digits before and after the decimal point as not being fixed; that is, the decimal point "floats". Some software applications fix the number of digits before and after the decimal point. However, most software applications use floating-point numbers because they can represent a larger range of numbers.

Floating-point numbers use two main standards for accuracy: single-precision and double-precision. With single precision numbers, the first seven significant digits are considered accurate. The first non-zero digit is considered the first significant digit. In the following examples, the bolded digits are considered significant.

- **123.4567**89
- **1,234.567**89
- **1,234,567**,890
- 0.**1234567**89
- 0.000**1234567**89

Double-precision numbers are similar to single-precision numbers except the first 15 significant digits are considered accurate.

Software applications, including RapidResponse, internally store floating-point numbers as binary numbers. This means they might not have a precise representation. For example, take the number 1.23456789. If this value was stored as a single-precision number, it would be 1.2345679. If the single-precision value was then stored as, or converted to, a double-precision number, it would be 1.2345678806304932.

When working with floating-point numbers, especially single-precision numbers that use many significant numbers, you might encounter some unexpected results from certain calculations. For example, if you are summing many numbers which are stored as single precision and use more than seven significant digits, the result might include unexpected values in the position of the sixth, seventh, and eighth significant digits.

RapidResponse can store Quantity input data as single-precision numbers using the QuantitySingle data type, or as double-precision numbers using the Quantity data type. However, for single-precision numbers, the RapidResponse analytics convert the data into double-precision numbers. In some cases this can produce unexpected results if using data that includes more than seven significant digits. For example, a series of numbers such as 1,234.56789 used in analytic calculations might produce unexpected results in the last three decimal places, especially as numbers are multiplied and compounded.

Storing Quantity input data as double-precision numbers means analytic calculations of data with more than seven significant digits will be more accurate. However, the Quantity data type uses 8 bytes of memory for each field and the QuantitySingle uses 4 bytes. Storing Quantity values as double-precision numbers might result in increased memory consumption. When creating custom quantity fields, you can choose whether to use the Quantity or the QuantitySingle data type.

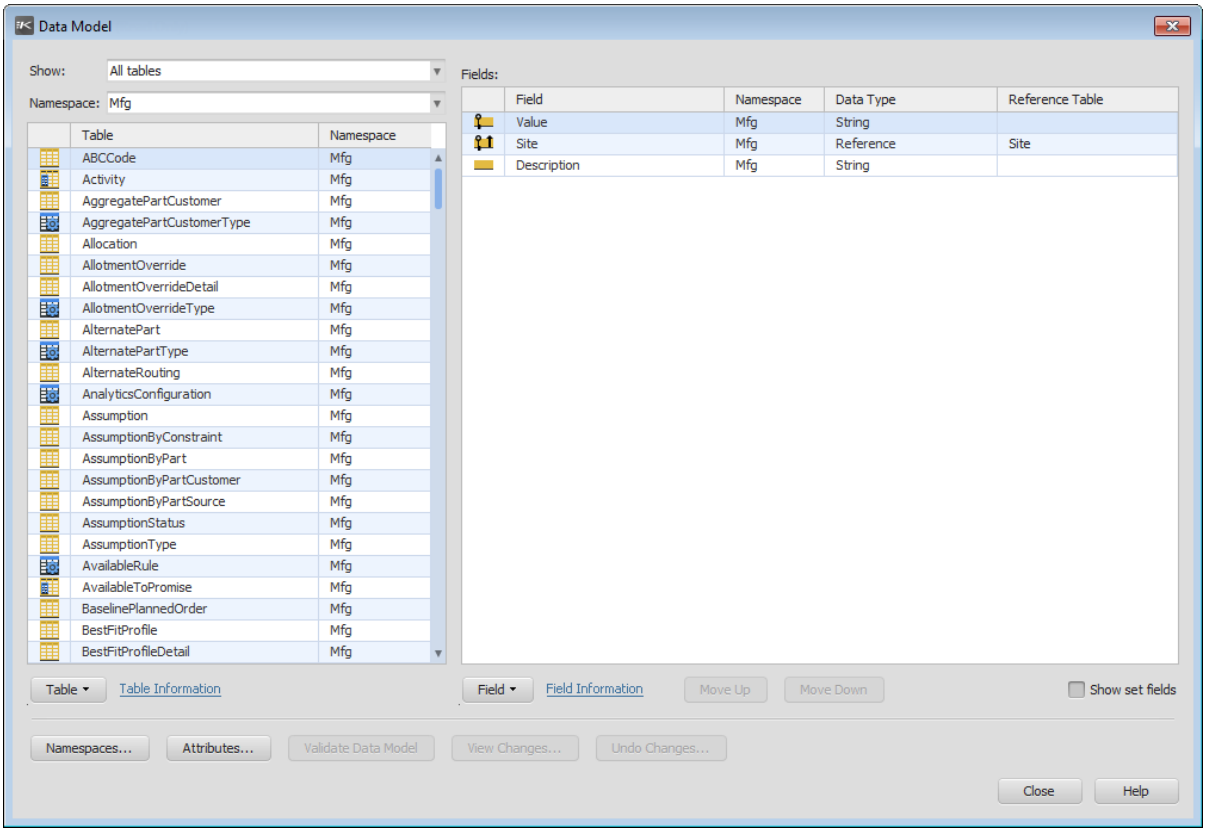
For more information about floating-point numbers and IEEE (Institute of Electrical and Electronics Engineers, Inc.) standards, see https://en.wikipedia.org/wiki/IEEE_754.

Data Model dialog box

System and data administrators can customize the RapidResponse data model using the Data Model dialog box. These administrators need to be granted permission to modify data integration settings.

This dialog box, as shown in the following illustration, provides information about all the tables and fields in the RapidResponse data model. It also provides data model reference information.

General users and authors can be given permission to open the Data Model dialog box. Access to the dialog box might help general users troubleshoot issues. It can also provide authors a better understanding of the data model to improve the resource authoring process.



To open the Data Model dialog box

1. Do one of the following:
   - **System and data administrators**—In the **Administration** pane, under **Data**, click **Data Model**.
   - **All other users**—On the **View** menu, click **Data Model**.
2. From the **Show** list, select one of the following:
   - **All tables**—displays all standard and custom RapidResponse input and control tables, as well as all standard RapidResponse calculated tables.
   - **Calculated tables—**displays all standard RapidResponse calculated tables.
   - **Control tables**—displays all standard and custom RapidResponse control tables.

- **Frequently used tables**—displays all tables that have been designated as frequently used. These allow you to define a group of tables you expect to frequently work with or modify.
- **Input tables**—displays all standard and custom RapidResponse input tables.
- **Tables with fields in namespace**—displays only tables with fields that belong to the namespace selected from the **Namespace** list. For example, for a namespace created by your company, this might include custom input tables you've created as well as standard RapidResponse input tables in the Mfg namespace that you've added fields to.

3. Optionally, from the **Namespace** list, select the namespace whose tables you want to view. The list of tables shown is then narrowed to those matching the selection in the **Show** list which also belong to the selected namespace.
4. If you want to display the set fields on each table, select the **Show set fields** check box.

To view table and field reference information

- Do one of the following:
  - To view help for a given table, select it from the **Table** box, and then click **Table Information**.
  - To view help for a given field, select it from the **Fields** box, and then click **Field Information**.

  For standard RapidResponse tables and field, the *RapidResponse Analytic and Data Model Guide* opens and displays information about the selected table or field. For custom tables and fields, a dialog box opens displaying properties and information provided by the user who added the table or field.

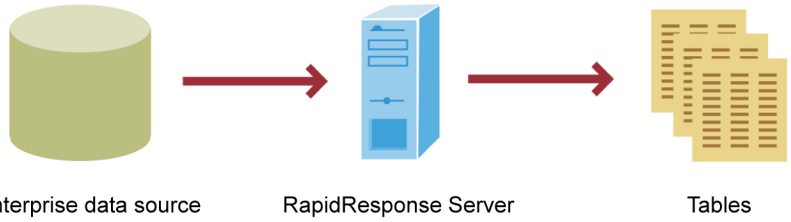
Tips:
- For more information about the Data Model dialog box, click the **Help** button.
- You can also access reference information for a given table by right-clicking it in the **Table** box and then clicking **Table Information.** Similarly, you can access reference information for a given table by right-clicking it in the **Field** box and then clicking **Field Information**.

CHAPTER 4: Introduction to the RapidResponse data model

A typical manufacturing system consists of items that need to be built or manufactured. Whether it be an aircraft or a bicycle, companies need to keep track of all the parts needed to build a product, who wants to buy the part, and how to replenish the supply once demand for the part increases. In order to manage the data required to keep track of a product and what's required to make, buy, sell, or ship it, the RapidResponse data model can be used.

With RapidResponse, data is extracted from your enterprise system and imported into the tables of the data model as shown in the following illustration. Each of these table stores information related to a specific area of your demand management or manufacturing operation such as SKUs, parts, bill of materials, shortages, customer orders, and work orders. These tables are editable which enables simulations to be performed on your data. Besides the tables which hold this imported data, the data model holds other tables which are populated by calculations performed by RapidResponse (for example, RapidResponse generates planned order recommendations). These tables are not editable, and their calculations are based on your imported data, and are configurable through processing rules.

Figure 4.1 Data imported into tables



Each table in the data model is made up of fields. Each field holds a single piece of data such as a part's number, low level code, or standard unit cost. A table also consists of records. Each record is a collection of fields that make up a single entry in your table. For example, the Part table holds information about each unique part in the data model.

In order to leverage the data in the RapidResponse database, it is important to understand how data is stored and organized. This chapter introduces you to the RapidResponse data model, how it is organized, and the basic data groupings.

In this chapter, you'll learn about:

RapidResponse data **150**
Products and structure **151**
Activity **152**

Controls 159

Note: For information about the RapidResponse calculations used to populate various tables in the data model, see "Part 2: Analytics" on page 1283.

RapidResponse data

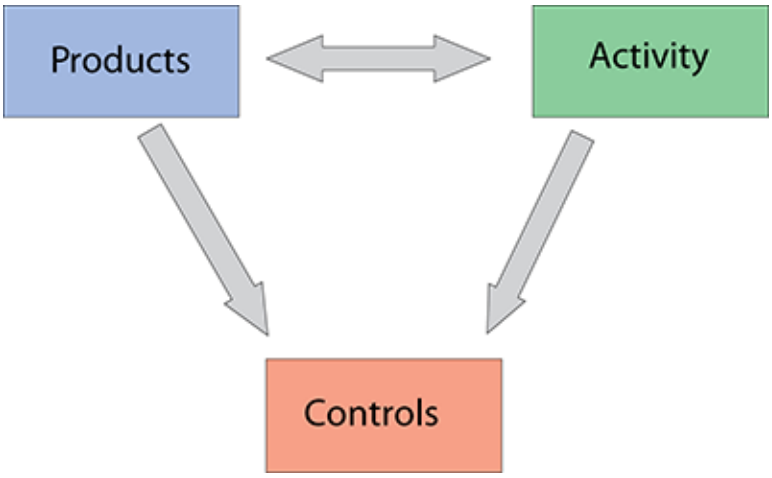
In an enterprise data system, all of the pieces of data required to manage the supply and demand for a product are linked together. The same is true for the RapidResponse Data Model. Although many different tables are used to store specific supply or demand related information, these tables are linked together where logically appropriate. For example, tables containing demand information for your parts link to the table where part information is stored.

All links between tables in the data model are bi-directional. This means that if Table X points to Table Y, then Table Y must point back to Table X. Each link from one table to another in the data model is of one of two types:

- **One-to-Many** – one record in the first table can link to many records in the second table. For example, a single part may have many customer orders.
- **Many-to-One** – many records in the first table link to one record in the second table. For example, there can be many customer orders for a single part.

Regardless of the links between them, the tables in the RapidResponse data model contain data belonging to one of three general groups as shown in the following diagram.

Figure 4.2 RapidResponse data



The following list briefly describes the three groupings of RapidResponse data discussed in this section.

- **Products and Structure**—Detailed information about all individual parts or SKUs, and shows the parts, raw materials, subassemblies, and intermediates that go into a parent assembly, as well as the quantity of each required to make an assembly. For more information, see "Products and structure" on page 151.

- **Activity**—Time-phased events that increase or decrease the inventory for a part. Typically, this involves a date and quantity associated with some activity that either consumes parts (demand) or provides parts (supply). Some activity data is imported directly from your enterprise data source and represents decisions that have already been made. (for example, open work orders). Other activity data is calculated by RapidResponse (for example, planned orders). RapidResponse also includes consolidation and pegging tables that combine or associate different levels of supply and demand activity for reporting. For more information, see "Activity" on page 152.
- **Controls—**Processing rules typically set up during the implementation of RapidResponse that determine how the different RapidResponse calculations are carried out. These are used to ensure that RapidResponse processing behavior matches that of your enterprise data source. For more information, see "Controls" on page 159.

Products and structure

At the heart of the RapidResponse data model is the **Part** table. This table lists each unique part (or SKU) that has been imported into the data model. It also holds information on each of these parts such as a part's name (or number), description, material cost, and standard unit cost.

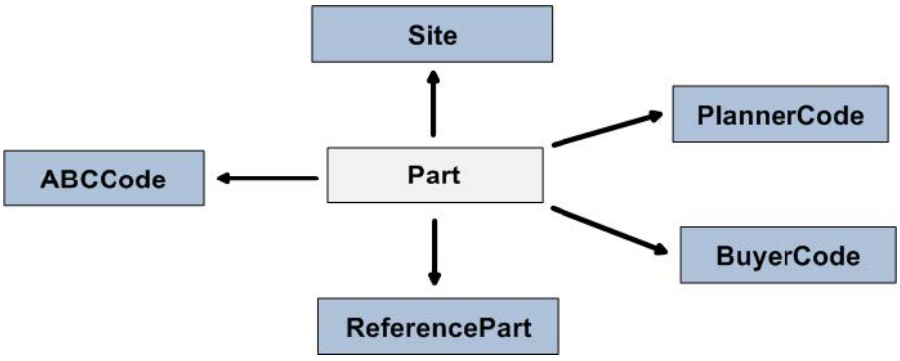
Besides the data contained directly on the Part table, the Part table links to other tables that contain part related data as shown in the following illustration. These tables allow for common part information typically associated with many different parts (such as abc codes, buyer codes, and planner codes), to be stored in just one place and then referenced from the **Part** table.

The **Part** table also has a reference to the **Site** and **ReferencePart** tables.

The **Site** table contains an entry for each unique site in the data model (for example, a particular factory or distribution center). Together a part's name and site make up its primary key and guarantee its uniqueness in the RapidResponse data model.

The **ReferencePart** table supports cross-referencing of a part's name with the name it is more commonly known by elsewhere. For example, a contract manufacturer can use the **ReferencePart** table to store the part names used and understood by a brand owner. The **ReferencePart** table might also be used by any manufacturer who wants to cross-reference two or more parts to indicate they should be treated as the same part (for example, if a new part numbering scheme is being implemented).

Figure 4.3 Part table and referenced

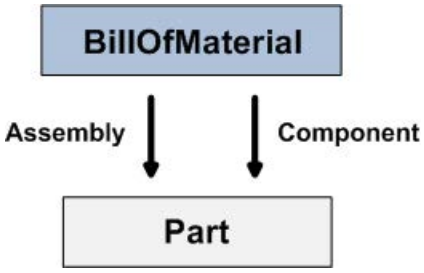


Besides a list of all parts and their attributes, RapidResponse needs to keep track of all the components required to build each part. This information is held in the **BillOfMaterial** table which references the **Part** table.

The **BillOfMaterial** table identifies parent /child relationships between assembly parts (products, assemblies and sub-assemblies), and their component parts (assemblies, sub-assemblies, and raw materials). For this reason, the **BillOfMaterial** table has 2 separate references to the **Part** table, one to define the assembly and another to define a component under that assembly. Each record in this table also contains details of the relationship between a given assembly and component. For example, the **QuantityPer** of the component required to make one unit of the assembly.

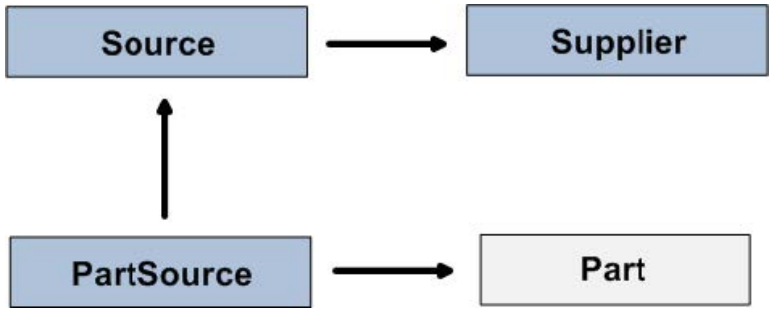
The relationship between the **Part** and **BillOfMaterial** tables is shown in the following illustration.

Figure 4.4 BillOfMaterial table defines how products are built



Another important table to understand when dealing with parts is the **PartSource** table. This table can be used to define multiple sources of supply for a single part as well as the planning attributes for that part and source relationship. Examples of multiple sources of supply for a single part includes parts supplied by more than one vendor, parts that can be made or bought, and parts that are transferred in from another internal plant. The **PartSource** table references the **Part** table and it contains information such as the lead times and costs associated with the part source. As shown in the following illustration, the **PartSource** table also references the Source table which contains delivery information and provides a reference to the **Supplier** table which identifies the part's supplier (could be either a vendor, work center, plant, and so on).

Figure 4.5 PartSource table defines multiple sources of supply for parts



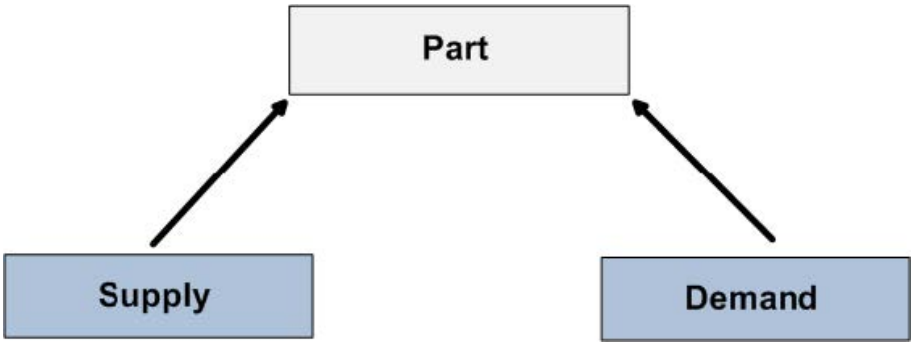
Activity

Once you have a part and all of the pieces required to build it, there has to be some activity in the system that drives demand for the part. Similarly, there must be some activity that generates or replenishes supply of the part as necessary.

Input activity

The RapidResponse data model contains tables into which you can import this supply and demand (or "activity") information.

Figure 4.6 Parts can have imported supply and demand

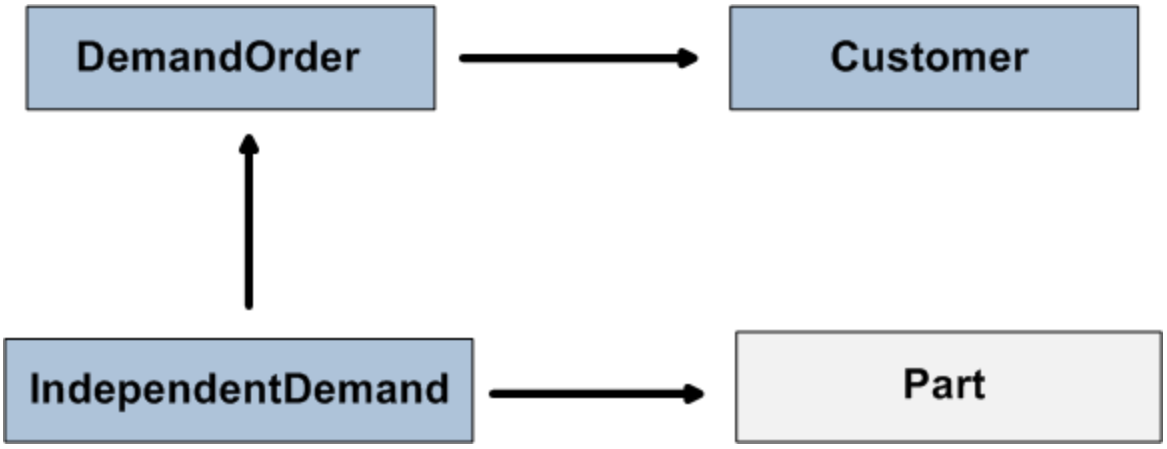


Independent demand is imported from your enterprise data source. It refers to demand not directly generated from the demand for other parts. For example, forecasted or actual customer demand for finished goods.

IndependentDemand table

The **IndependentDemand** table contains a record for each line item associated with an actual customer order or forecast. These records contain details such as due date, request date, and quantity associated with the line item. However, since a customer can place a single order that has many line items for each part, common header information for each independent demand (such as its order number or customer) is stored in the **DemandOrder** table. As shown in the following illustration, the **DemandOrder** table then links to the **Customer** table to identify the customer associated with the order.

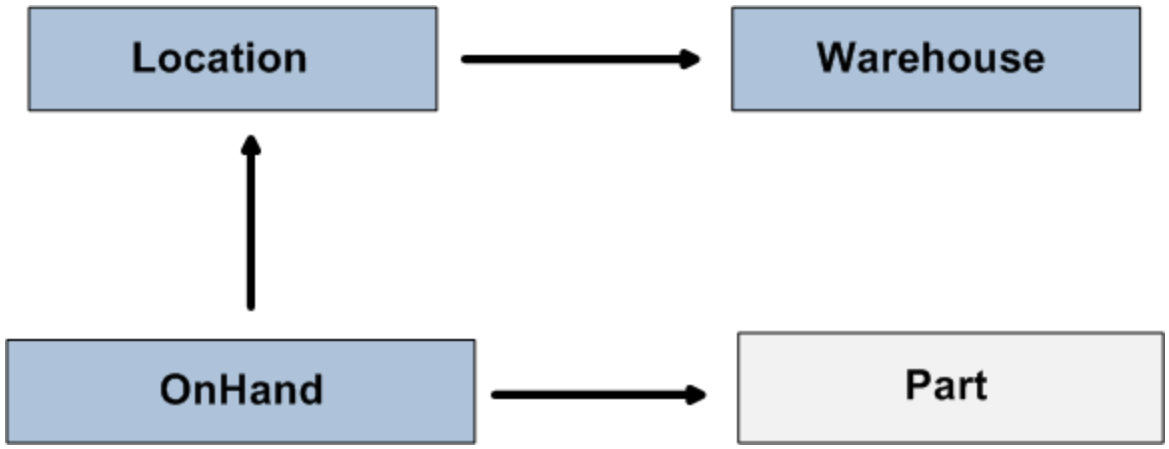
Figure 4.7 IndependentDemand table references



OnHand table

Another important table to understand when working with activity data is the **OnHand** table. This table holds the quantity of inventory for each part in a particular storage location within a warehouse. As shown in the following illustration, this table links to the **Location** table and subsequently to the **Warehouse** table which store the actual location and warehouse values respectively.

Figure 4.8 OnHand table references

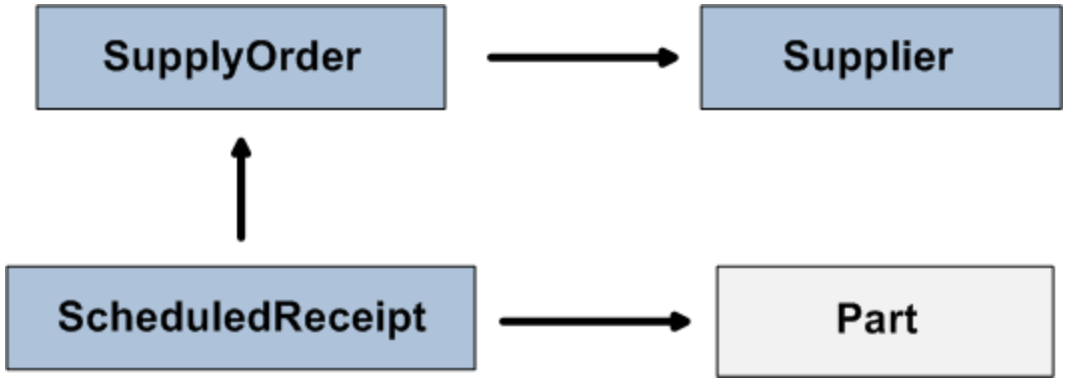


ScheduledReceipt table

Each record in the **ScheduledReceipt** table represents a single line item on a supply order. It stores firm orders with an assigned due date and quantity, such as work orders or purchase orders. These orders are imported from the enterprise data source, although **ScheduledReceipt** table also contains some fields populated by Rapid Response calculations (for example, RapidResponse calculates a rescheduled due date for each order).

As shown in the following illustration, the common header information about each order (such as the order Id and supplier) is stored in the **SupplyOrder** table which is referenced from the ScheduledReceipt table. The **SupplyOrder** table then references to the **Supplier** table which holds all suppliers defined in the system. A supplier may be a vendor for a purchase order, a work center for work orders, or a plant identifier for inter-plant orders.

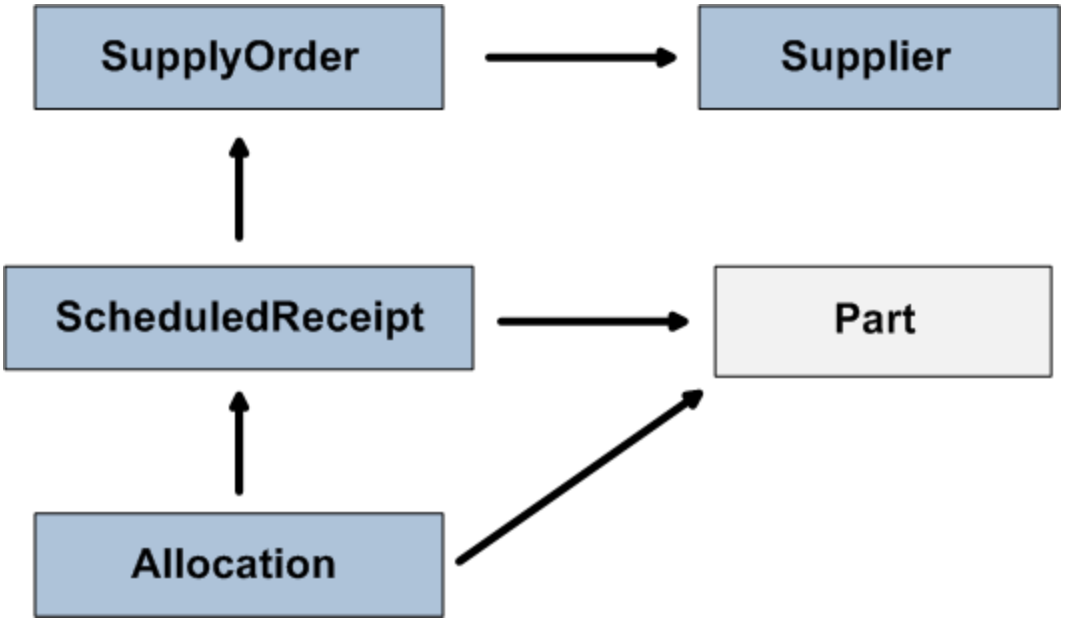
Figure 4.9 ScheduledReceipt table references



As shown in the following illustration, the **ScheduledReceipt** table is referenced by the **Allocation** table which is used to store allocations (dependent demands) generated from a work order for a make item. If

you do not import allocations from your enterprise data source, RapidResponse can calculate them for you as discussed later in this chapter. That is, the **Allocation** table is used only for those allocations imported from your enterprise data source (typically, this is done at a time close to when the order is being released to the shop floor, or when you have deviated from the standard bill of materials).

Figure 4.10 Allocation table for importing dependent demands



Calculated activity

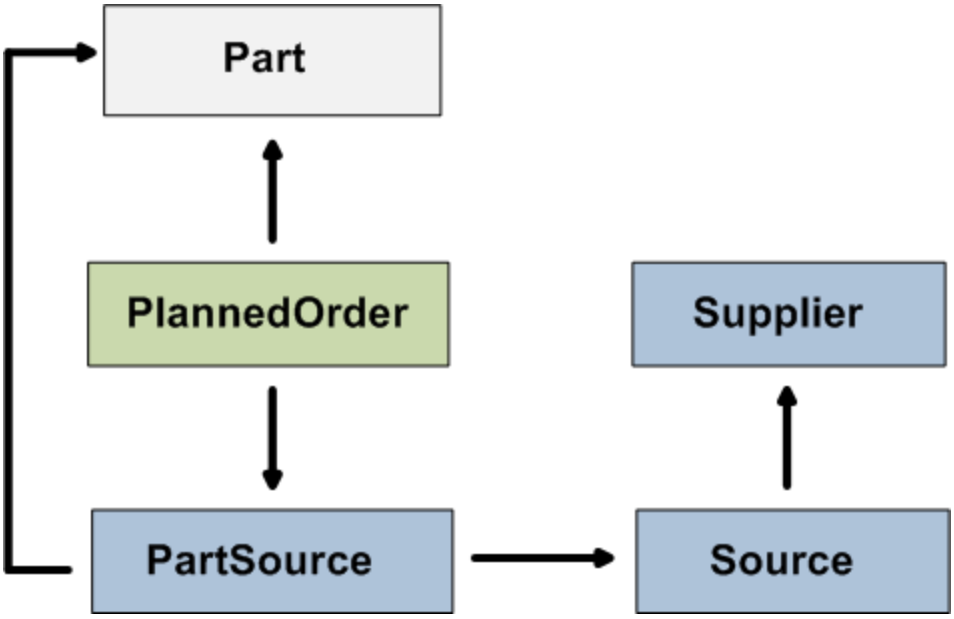
The RapidResponse data model also contains calculated tables that hold activity data not input.

PlannedOrder table

The **PlannedOrder** table is a calculated table providing recommendations for new supply orders to be generated.When there are not sufficient supply quantities in **ScheduledReceipt** or **OnHand** records to satisfy demands, RapidResponse attempts to create planned orders to satisfy demand. Unlike the **ScheduledReceipt** table, the **PlannedOrder** table does not contain data imported from the enterprise data source. Instead it contains new recommended planned orders generated by RapidResponse analytic calculations. Parameters like days supply and lot sizing can affect the size and frequency of planned orders generated as discussed later in this guide.

Each **PlannedOrder** record contains details of the planned supply such as due date, order quantity, and a reference to the part the order is for. The **PlannedOrder** table references not only the part associated with the supply, but also a part source. This is made through a link to the **PartSource** table which is a calculated reference made by RapidResponse when the order is generated. This is shown in the following illustration.

Figure 4.11 PlannedOrder and associated tables



Note: For each record generated in the **PlannedOrder** table, a corresponding record is generated in the **CTPPlannedOrder** table. This table references the PlannedOrder table and contains capable-to-promise details relating to the planned order (for example, availability details).

NewAllocation and PlannedAllocation tables

The RapidResponse data model also includes the **NewAllocation** and **PlannedAllocation** tables each of which hold calculated allocations (dependent demands) generated by RapidResponse.

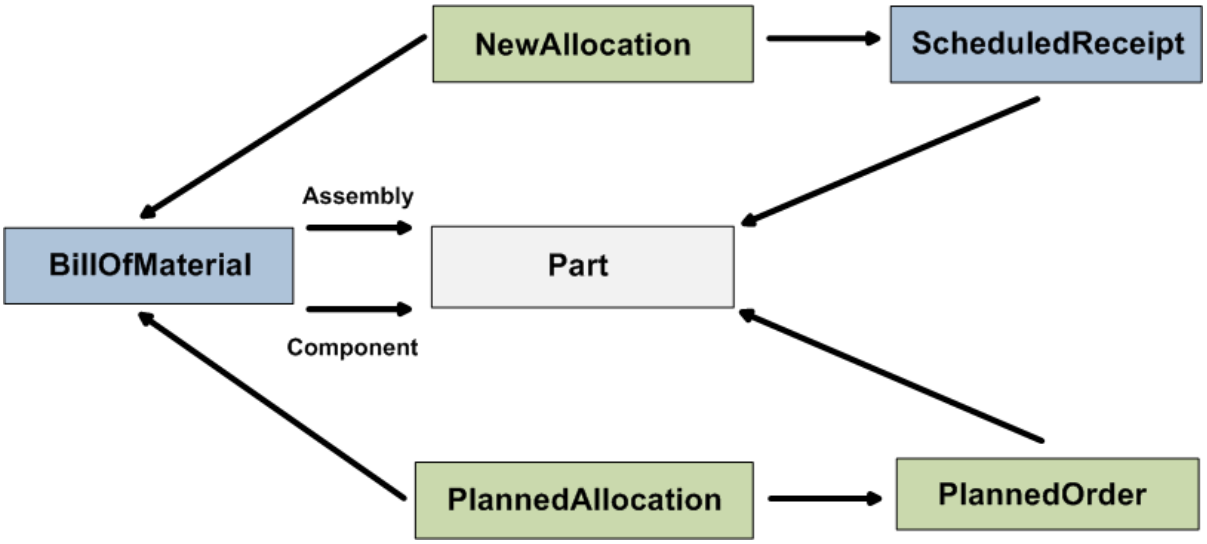
As discussed earlier in this chapter, the input **Allocation** table is used to store dependent demands imported from your enterprise data source and tied to a particular scheduled receipt. This might be done, for example, when the order is close to being released or when the standard bill of materials has been deviated from. Typically, though, it is not necessary to import dependent demands on a scheduled receipt.

For those scheduled receipts which do not have records imported into the **Allocation** table, the **NewAllocation** table is then used to store calculated allocations generated by RapidResponse calculations.

Similarly, the **PlannedAllocation** table contains calculated dependent demands generated because RapidResponse generated a planned order for a parent part.

Records in the **NewAllocation** and **PlannedAlllocation** tables are calculated by the explode calculation for each BillOfMaterial record. As such, these tables both reference the BillOfMaterial table as well as the corresponding **ScheduledReceipt** or **PlannedOrder** record that drove the dependent requirement.

Figure 4.12 NewAllocation and PlannedAllocation table hold calculated dependent demands



Consolidation tables

RapidResponse also includes several calculated "consolidation" tables. These tables combine multiple sources of supply and/or demand records into a single table. For example, as discussed previously, RapidResponse stores calculated dependent demands in both the **NewAllocation** and **PlannedAllocation** tables and also allows dependent demands to be imported into the **Allocation** table. For a single view of dependent demands, records from all of these tables are consolidated into the calculated **DependentDemand** table.

The following outlines some key consolidation table in RapidResponse:

Table 4.1: Consolidation tables

Table	Description
DependentDemand	Combines input allocations, new allocations, and planned allocations together to show all dependent demands.
Demand	Combines dependent demand and independent demand together to give the total demand picture. Includes only those demands processed by Netting calculations
Supply	Combines multiple sources of supply such as scheduled receipts, planned orders, and inventory transfers to give the total supply picture. Includes only those demands processed by Netting calculations.
Activity / CTPActivity	Combines all supply and demand information together in a single place. Activity reports details from Netting calculations and CTPActivity reports details from Capable-to-Promise calculations.

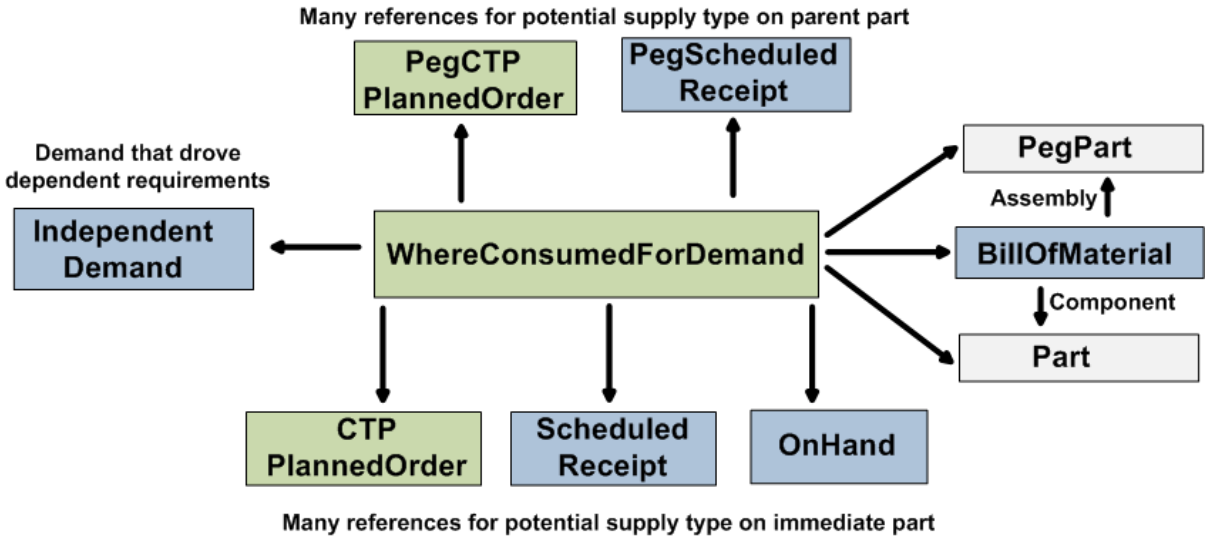
Pegging tables

RapidResponse includes many other calculated full-level pegging tables you might find useful for reporting and analysis purposes. This includes tables that trace allotments of supply to the higher level demands (or supplies) that consume them.

WhereConsumedForDemand table

For example, the WhereConsumedForDemand table can be used to peg independent demands to the set of supplies they consume. Each record in this table reports details of a given supply (for example, an onhand quantity, scheduled receipt or planned order), the immediate parent supply that it satisfies, and the driver independent demand ultimately responsible for driving demand down the structure. This make it possible to show all supplies that ultimately satisfy a given independent demand by reporting all of the individual supply allotments between the top-level demand and its lowest level component(s).

Figure 4.13 References from the **WhereConsumedForDemand** table.



The following outlines some the main tables used for reporting supply allotment details in RapidResponse.

Table 4.2: Tables that contain pegging information

Table	Description
SupplyDemand	Populated by capable-to-promise calculations, but contains records linking the supply of components to the next level demands that consume them (single-level only). Useful when you want to match demands to the allocated supply at a single part level only.
WhereConsumed	Pegs supply records to the end item demands which consume them. Useful when you want to show pegging information across all levels in the structure with a focus on the supply that is being consumed.

Table 4.2: Tables that contain pegging information

Table	Description
WhereConsumedForDemand	Pegs independent demand records to the set of supplies they consume. Useful when you want to show pegging information across levels in the structure with a focus on the demand that is driving the activity.
WhereConsumedForSupply	Pegs supply records to the higher level production orders that consume them. Useful when you want to see all material required for any order in the supply structure or that are ultimately used in satisfying a top-level supply.
WhereConsumedForForecast	Pegs consensus forecast records to the set of supplies they consume. Useful when you want pegging information across levels in the structure with a focus on demands generated from the sales and operations planning process in RapidResponse.

Controls

The RapidResponse data model contains control data. This data is found in control tables each of which contains one or more configurable rules or values. The configuration of these rules determines the processing applied to your imported data and the results of the calculations seen in the RapidResponse data model.

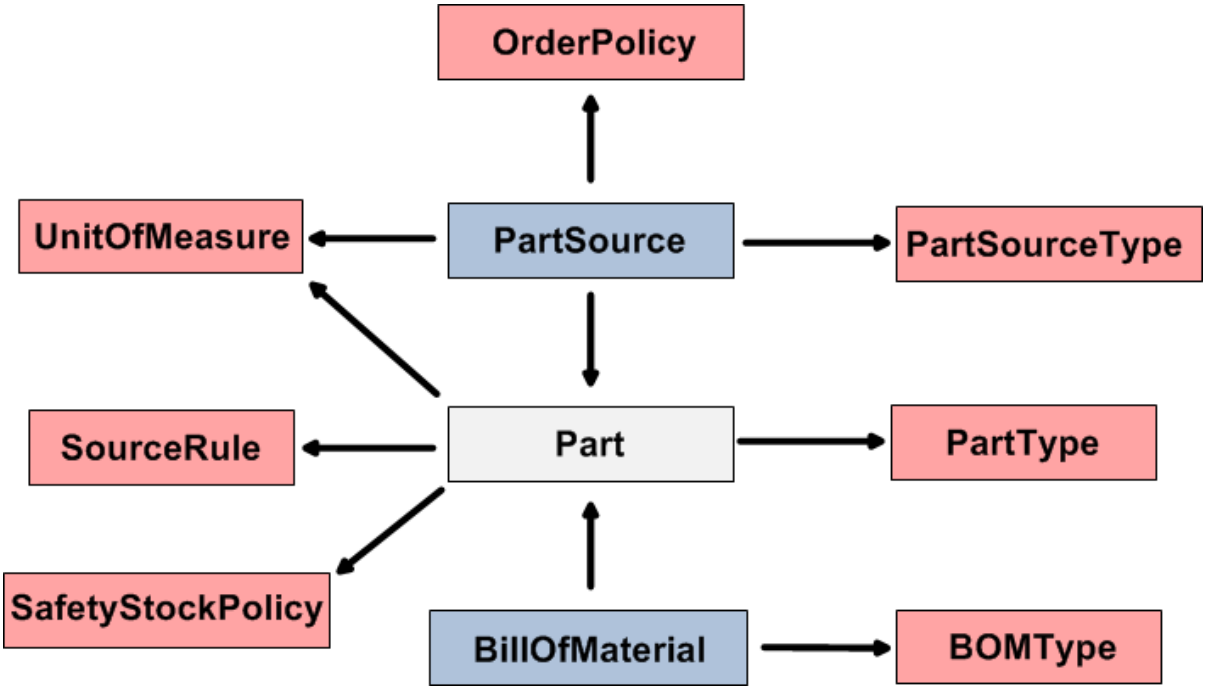
Typically, these control tables are set up once during a RapidResponse implementation and are intended to correspond to the types of data, codes, and associated processing rules found in the enterprise data source. This ensures that the data generated by RapidResponse is familiar to what you have been accustomed to seeing in the enterprise data source. It is also possible to change these controls if, for example, you wanted to simulate the impact of a global policy change.

Control tables are referenced from many input tables in the data model.

Control tables (on products and structure)

As shown in the following illustration, control tables are referenced from many tables containing imported enterprise data about products and structure.

Figure 4.14 Examples of control tables referenced by products and structure tables



The following list describes some of the main control tables referenced by product and structure tables in RapidResponse.

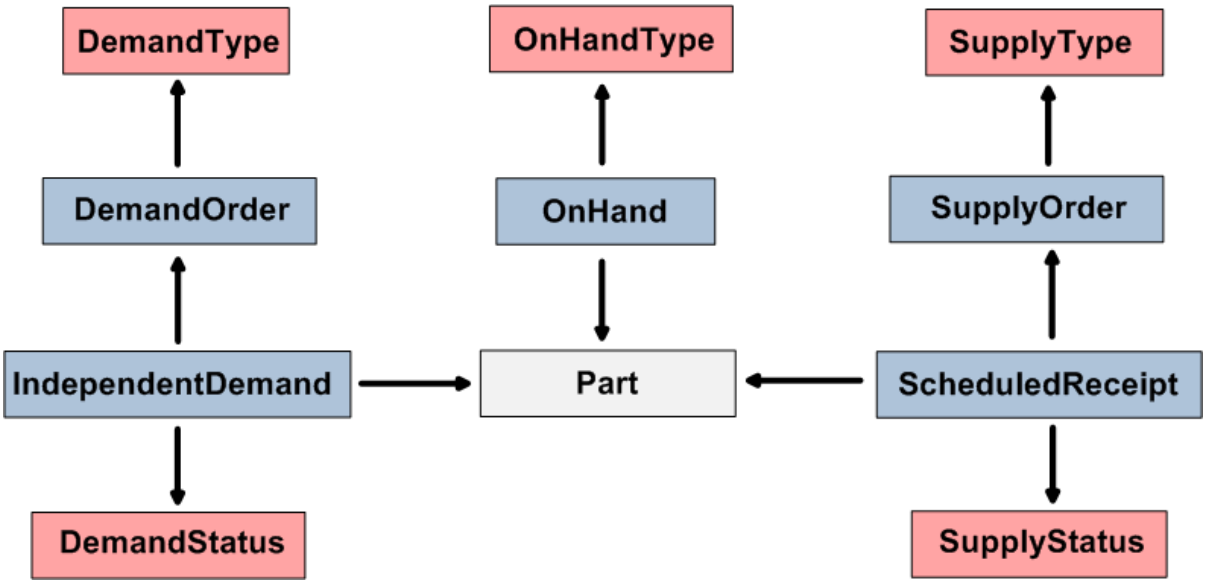
Table 4.3: Descriptions of control tables referenced by products and structure table

Table	Description
PartType	Sets how the part is processed by RapidResponse calculations. For example, can planned orders be created for the part.
BOMType	Identifies different types of bill of material records and the rules for processing them. This includes things such as blowthrough logic (phantom parts), scrap rules and effectivity rules.
PartSourceType	Sets the characteristics of each potential supply source. For example, it controls the effectivity of sourcing features and determines the type and status of planned order's when supplies are required using this source.
OrderPolicy	Controls details of planned order generation from this source. For example, lot sizing policies and lead time rules for a part source on defined on this table.
SourceRule	Defines how part sources are handled when a part has more than one active source.
UnitOfMeasure	Defines, and allows conversion between, different unit of measure codes. For example, supplier units to inventory units.

Control tables (on activity)

As shown in the following illustration, control tables are referenced from tables containing imported enterprise activity data.

Figure 4.15 Examples of control tables referenced by activity tables



Examples of supply and demand control tables

The following list describes some of the main control tables referenced by input activity tables in RapidResponse.

Table 4.4: Descriptions of control tables referenced by supply and demand tables

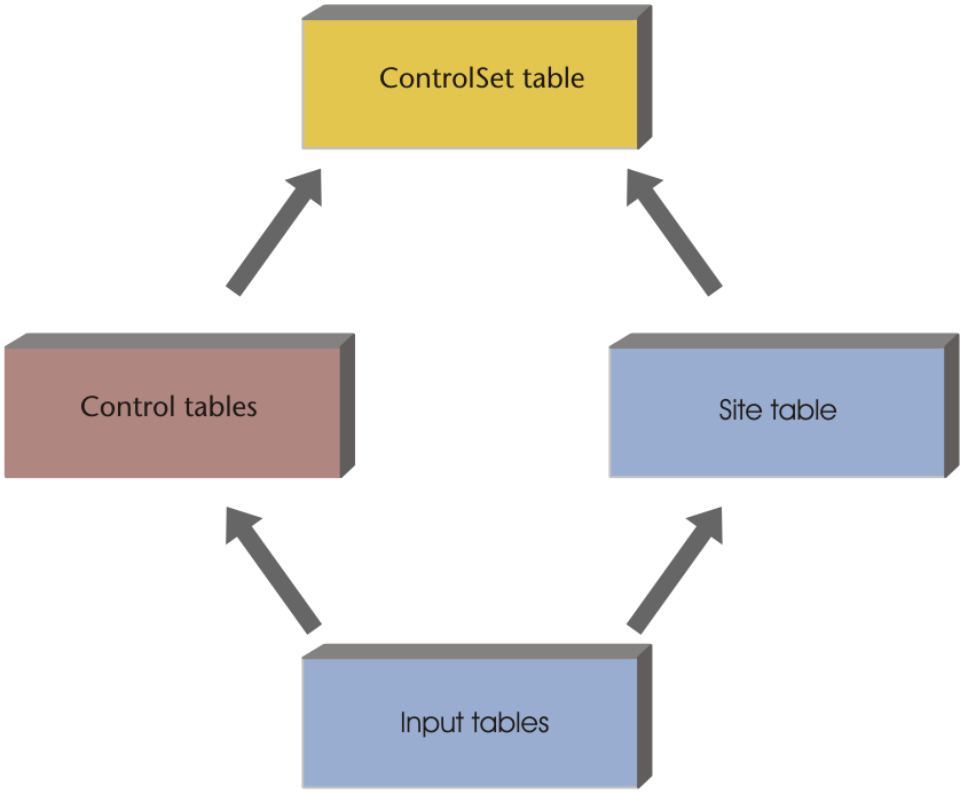
Table	Description
OnHandType	Sets whether a given stock of inventory is included in Netting calculations.
SupplyType	Defines processing rules for handling a particular supply order and its associated line items. For example, can allocations be generated for the line items. Also used by the **PartSourceType** control table to define characteristics for processing planned orders using this part source.
SupplyStatus	Defines processing rules for handling a particular line item (scheduled receipt). For example, a line item can be reschedulable. Also used by the **PartSourceType** control table to define characteristics for processing planned orders using this part source.
DemandType	Defines processing rules for handling a particular demand order and its associated line items. For example, should it be treated as actual or forecasted demand.
DemandStatus	Sets the processing rule for a line item (independent demand). For example, you can specify that the item be ignored by RapidResponse calculations.
ShipmentPolicy	Sets whether a given independent demand can be broken into partial shipments.

Control sets

RapidResponse allows for named groupings of control table settings known as control sets.

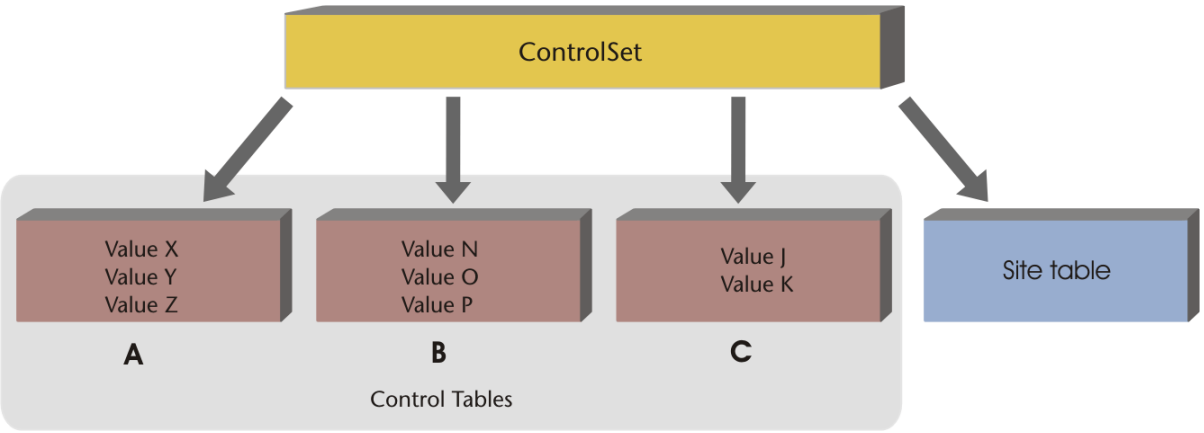
All control set values are stored in the ControlSet table. This table is referenced by all control tables other than the HistoricalDemandCategoryType table. As shown in the following illustration, the ControlSet table is also referenced by the Site table. This reference indicates the control set that input data and its controls at a given site are typically expected to use.

Figure 4.16 References to ControlSet table



As shown in the following illustration, each given control set is made up of all Values on any of the tables listed above that reference that control set. Using control sets you can then easily show only those relevant control tables values for a particular type of RapidResponse site or configuration. Control sets also allow a defined group of control settings to be copied, modified, and re-used at other installations with similar data configurations.

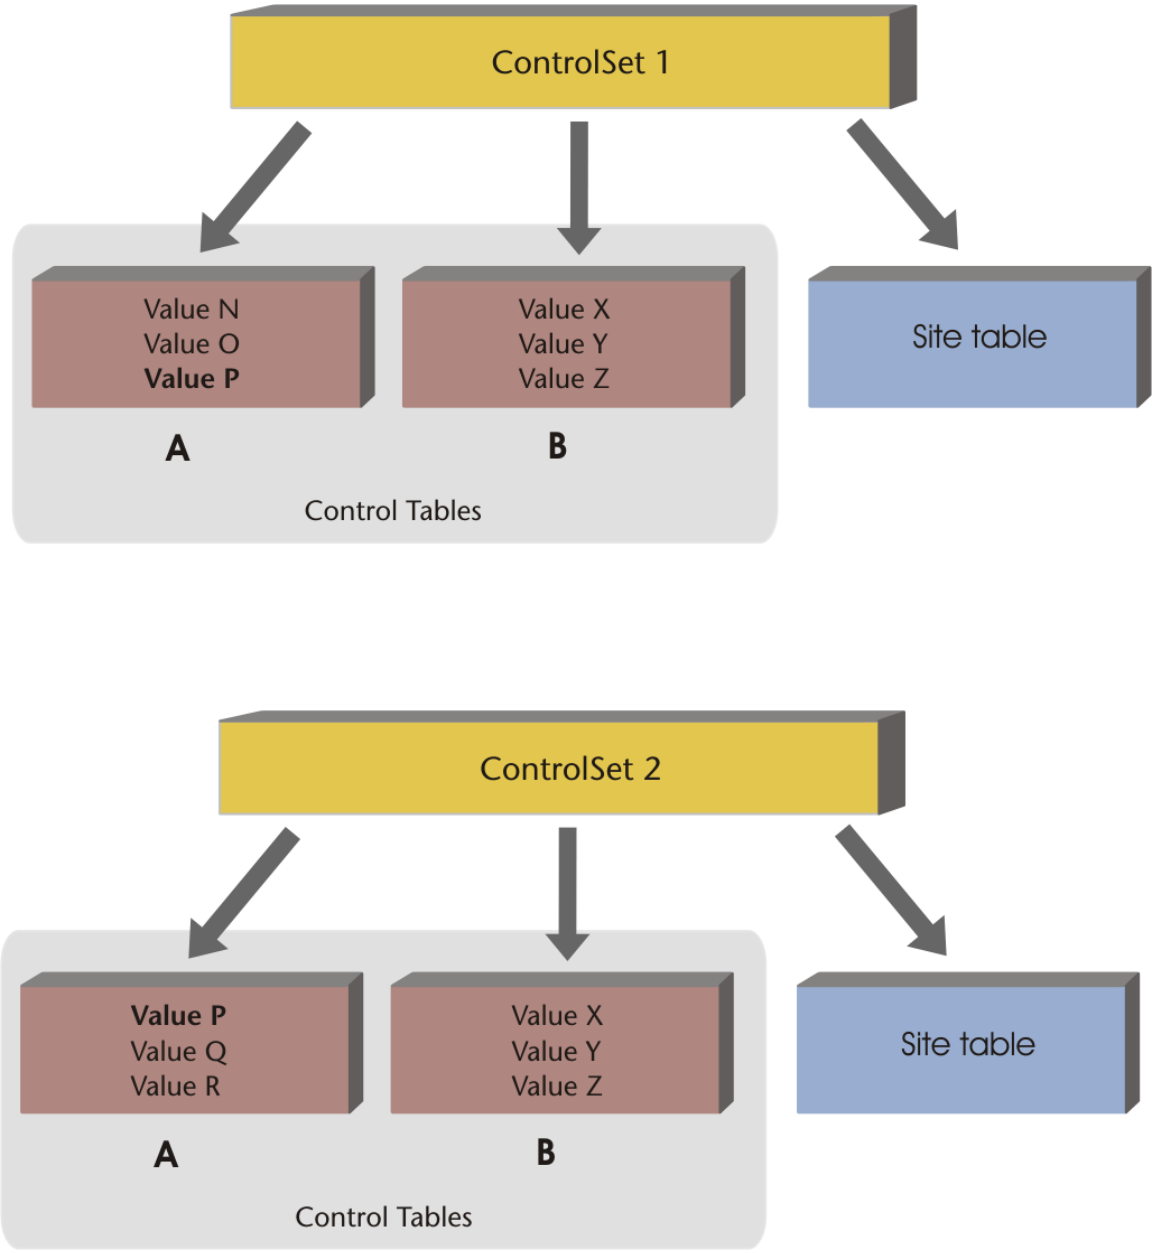
Figure 4.17 Values belonging to a single control set



Control sets also allow for the possibility of duplicate control values existing across sites and each being associated with different behaviors or properties. For example, in the following illustration a value of "P" exists on Control table A in both Control Set 1 and Control Set 2. If Control table A is assumed to

represent the PartType table, then "P" might indicate a part type of "purchased" in one control set, but a part type of "phantom" in another control set. By allowing duplicate control values that potentially represent different behaviors, control sets protect against data collisions in cases where multiple data sets are merged together in RapidResponse.

Figure 4.18 Values belonging to different control sets



Notes:

- For more information about the ControlSet table, see "ControlSet table" on page 253.
- For more information about managing control sets, see the *RapidResponse Administration Guide*.

CHAPTER 5: Optional applications and tables

This guide describes all the standard and optional tables, fields, and analytics available with RapidResponse.

RapidResponse offers optional application options to help manage many supply chain planning processes in different functional areas. RapidResponse also includes optional functional capabilities that your company might enable to support business processes.

The deployment of optional applications and capabilities impacts the RapidResponse client and the analytic calculations.

Optional analytics and the data model 165
Optional RapidResponse capabilities 166
Optional RapidResponse applications 170

Optional analytics and the data model

Optional RapidResponse applications and capabilities and are enabled through license keys. License keys are provided by Kinaxis Customer Services in a file that is imported into RapidResponse by a system administrator. If you are using the On-Demand version of RapidResponse, contact your Master Administrator at Kinaxis for more information about enabling optional applications and capabilities. If you are using the On-Premises version of RapidResponse, review the *RapidResponse Administration Guide* for more information.

The RapidResponse client might hide tables and fields associated with optional applications and capabilities that have not been enabled by your company. As such, resource authors, or users who create reports, might not have access to tables and fields that have not been enabled. Resource authors cannot create a report based on a table that has not been enabled or use a field that references a table that has not been enabled. If you import data into tables that have not been enabled, you will not be able to view or use this data.

If a table contains a field that references a table that has not been enabled, then that field is not available to resource authors. For example, the Operation table includes a field that references the Model table. If the Model-Unit Effectivity capability is not enabled then the Model table is not available and the reference from the Operation table is also not available.

In addition, analytic calculations associated with optional applications and capabilities might not be calculated. As such, calculated fields associated with these optional applications and capabilities remain empty.

The tables, fields, and analytics associated with optional applications and capabilities are not explicitly noted in this document. Contact your Kinaxis Customer Service for more detailed information.

Optional RapidResponse capabilities

This section describes the following optional capabilities available with RapidResponse:

- "Campaign Planning" on page 166
- "Constraint Manager" on page 166
- "Model Effectivity and Unit Effectivity " on page 167
- "R integration" on page 168
- "Self-Healing Supply Chain" on page 169

Campaign Planning

Campaign planning is typically used in process industries where supplies are produced in batches and efficiencies can be gained from sequencing and processing those batches as a contiguous group. When campaign planning logic is enabled, supplies for a part are planned in defined batch sizes and grouped together into production campaigns.

For more information, see "Campaign planning" on page 1707.

Fields and options available with Campaign Planning

- “CampaignPlanning” option in OrderPolicy.MaximumUsage
- PlannedOrder.CampaignIndex
- SourceConstraint.CampaignFixedConstraintFactor
- SupplyOrder.CampaignIndex

Constraint Manager

Constrained planning logic determines the date when supplies and demands are available with respect to one or more constraints associated with the source of supply. Constraints can be fixed or variable factors representing the capacity of a process or supplier (for example, the number of units per day a production line can produce). A single source of supply can be constrained (restricted) by multiple constraints.

Tables available with Constraint Manager

- Constraint
- ConstraintAvailable
- ConstraintLoad
- ConstraintSpreadLoad
- ConstraintType

- ConstraintUnitOfMeasure
- ConstraintUsed
- FLPConstraint
- PeriodConstraintLoad
- SourceConstraint
- TrialConstraintShortage
- TrialConsumption

Constrained planning with Constraint Manager

The **ConstaintType** table holds control settings used in constrained planning. The **ProcessingType** field on this table determines how constraints are applied and impacts load, available date, and other calculations.

If a full Constraint Manager license is applied, then all **ConstraintType.ProcessingRule** settings are available and constrained supply plans can be generated. That is, any of the "Constrained", "CumMax", "LoadOnly", "PlanningOnly", "Unconstrained", and "UnconstrainedPlan" options can be applied to a constraint.

However, if a limited load-only Constraint Manager license is applied, then only the "LoadOnly" and "Unconstrained" options are available and constrained supply plans cannot be generated (though all tables listed above are still visible).

Note: In the absence of any Constraint Manager license, supply planning is always unconstrained and the tables listed above are not visible.

Model Effectivity and Unit Effectivity

Model and Unit Effectivity are grouped as a single capability (Model-Unit Effectivity). Effectivity is a method for determining if a bill or operation record is used to generate dependent demand. Enabling this capability also enables the use of the Model control in worksheets. For more information about the analytic calculation, see "Model and Unit Effectivity calculations" on page 1737.

Tables available with Model-Unit Effectivity

- BOM_MUECumLead
- Model
- MUEPoolNetting
- Part_MUECumLead
- Part_MUEPoolValidation

The following fields are only available if the Model-Unit Effectivity is enabled.

Activity.StartUnit	FlatBillUp.FirstUnit	Operation.LastEffectiveUnit
Allocation.StartUnit	FlatBillUp.IsModelEffective	Operation.StartUnit
AvailableToPromise.StartUnit	FlatBillUp.LastUnit	Part.NextUnit

R integration

RapidResponse provides optional integration with the R programming language. R is integrated with RapidReponse to perform advanced statistical calculations for the following features:

- Statistical forecasting using the Rforecast model. For information, see "Rforecast" on page 2039.
- Advanced methods of outlier detection (stl, tsclean methods) in historical data in demand planning (data cleansing) and inventory planning and optimization (safety stock).
- Advanced statistical forecasting capabilities using multiple linear regression models. For more information, see "Multiple Linear Regression forecasting models" on page 2042.

Integration with R in RapidResponse is only available if the optional Rforecast capability has been enabled, and is available only with the On-Demand RapidResponse Service. In these cases, Kinaxis will deploy a distribution of specific standard 'R' package and ensure proper configuration with your company's instance of RapidResponse. Every effort will be made to keep these as up to date as possible. However, Kinaxis does not offer any services to deploy packages other than the specific set, nor to alter the content of the specific standard 'R' packages.

To learn more about the R, see www.r-project.org.

Tables available with Rforecast capability

- RParameter
- RParameterName
- RParameterSet

Fields and settings available with Rforecast capability

- BestFitProfileDetail.RParameterSet
- ForecastItemParameters.RParameterSet
- "Rforecast" option in ForecastItemParametersType.ForecastModel
- "RtslError" option in OutlierType.DataRule
- "Rtclean" option in OutlierType.DetectionRule

Note: For information about using R to generate the statistical forecast, see "Rforecast" on page 2039.

Self-Healing Supply Chain

The Self-Healing Supply Chain is only available if it has been enabled, and is only available with the On-Demand RapidResponse service. In these cases, the Self-Healing Supply Chain data model and calculations will be available. For more information, see "Self-Healing Supply Chain" on page 2135.

RapidResponse provides the Self-Healing Supply Chain. The Self-Healing Supply Chain uses machine learning to automatically detect and correct deviations in parameters used in supply planning data.

Tables available with Self-Healing Supply Chain

- AutomatedLeadTimeType
- AutomatedYieldType
- Cluster
- ClusterProperty
- HistoricalReceipt
- HistoricalReceiptHeader
- HistoricalSupplyActual
- ItemSource
- ItemSourceCandidate
- ItemSourceFitOutput
- ItemSourceFitOutputClass
- ItemSourceFitOutputForecastModel
- ItemSourceFitOutputValueName
- ItemSourceHistoricalSupplyCategory
- ItemSourceIntervalEffectivePartSource
- ItemSourcePartSourceEffectivityInterval

- ItemSourcePartSourceHistoricalLeadTime
- ItemSourcePartSourceHistoricalReceipt
- Job
- ProjectedLeadTime
- ProjectedYield

Optional RapidResponse applications

RapidResponse supports the following optional applications:

- Order Fulfillment
- Sales and Operation Planning
- Inventory Management
- Inventory Planning and Optimization
- Master Production Scheduling
- Supply Action Management
- Demand Planning
- Aggregate Supply Planning
- Capacity Planning - Constraints
- Capacity Requirements Planning
- Distribution Requirements Planning
- Engineering Change Management
- Supplier Collaboration
- Integrated Project Management
- Self-Healing Supply Chain

Deploying optional applications controls the visibility of tables and fields. It also controls whether some analytics are calculated.

CHAPTER 6: Input tables

This chapter describes each input table in the RapidResponse data model, along with all the input fields it contains. For those tables that contain either calculated or set fields, the details of these fields are described separately, immediately after the input fields.

RapidResponse contains input tables belonging to the Mfg namespace that store data imported from your enterprise data source. This includes data such as part and bill of material information, customer orders, and work orders. For the most part, this data is editable. However, some tables contain calculated fields. This data is not imported from your enterprise data source, but is instead generated by RapidResponse calculations. For example, in the ScheduledReceipt table, RapidResponse calculates fields such as the AvailableDate and RecommendedDate associated with an order.

RapidResponse also contains input tables belonging to the ProjMgmt namespace that store data imported from your project management application. This includes data such as project details, the work tasks that comprise each project, and the resources assigned to complete project tasks. Many of the tables in this namespace contain both input and calculated fields. However, when using the predefined project management resources included with RapidResponse, many input fields are populated by values inserted into other tables, and many calculated fields are editable. For example, records are added to the WBS table when inserting new Task table values.

In this chapter, you'll learn about the following:

ABCCode table

This table lists valid ABC codes which organize parts into groups based on annual dollar volume or other criteria. These are used to identify those parts which have the most impact and should be closely controlled.

This table's **Site** field is optional, and a system or data administrator can choose whether it uniquely identifies records in the table, or is ignored in queries, and not shown in insert definitions, dialog boxes, or the Data Sources and Mapping window.

Table 6.1: ABCCode (Mfg) fields

Field name	Description	Data type	Key
Description	A description of this ABC code.	String	
Site	The site associated with this ABCCode. This field is optional. **Referenced table**: Site	Reference	Yes
Value	A unique identifier associated with this ABC code. For example, "A".	String	Yes

For more information about making the **Site** field optional, see "Modifying table and field properties" in the *RapidResponse Data Integration Guide*.

ABCCode table – calculated and set fields

The following describes the calculated and set fields in the ABCCode table. For an introduction to this table, and descriptions of its input fields, see "ABCCode table" on page 176.

Table 6.2: Calculated ABCCode (Mfg) fields

Field name	Description	Data type	Key
Parts	Set of parts associated with this ABC code.	Set	

Activity table

The **Activity** table defines all the individual work items that together form a process. In addition to a reference to the applicable process instance, each record in this table contains details such as the

activity name, duration, and start day. It also reports calculated details such as activity start and finish dates.

Table 6.3: Activity (ProcOrch) fields

Field name	Description	Data type	Key
Duration	An input value that defines the duration of the activity.	Integer	
Id	A unique string identifier for this task.	String	Yes
Name	A name for the activity. This value should make the activity easy to recognize	String	
Override Notifications	Specifies whether the global notifications for the activity are overridden or not.	Boolean	
ProcessInstance	The name of the process instance that this activity belongs to. **Referenced table:** ProcessInstance	Reference	
SortKey	Defines the sequence of this activity.	String	
StartDay	The day in the process instance that this activity is planned to start in relation to the first day of the process instance.	Integer	

Activity table – calculated and set fields

The following describes the calculated and set fields in the Activity table. For an introduction to this table, and descriptions of its input fields, see "Activity table" on page 176.

Table 6.4: Activity (ProcOrch) fields

Field name	Description	Data type	Key
ActualFinishDate	If the activity has no assignment, the date is the expected finish date, if it falls after **RunDate.FirstDate**. If the activity has assignments, the date is the date of the last assignment to be completed.	Date	
ActualStartDate	If the activity has no assignment, the date is the expected start date, if it falls after **RunDate.FirstDate**. If the activity has assignments, the date is the date of the first assignment to begin work on the activity.	Date	

Table 6.4: Activity (ProcOrch) fields

Field name	Description	Data type	Key
CalcDuration	The calculated duration of an activity. For activities that are not sub-processes, the input duration is used. For the sub-processes, the **CalcDuration** is the summary of the durations of the child activities.	Integer	
CalcStartDay	For activities that are not sub-processes, the input StartDay is used. For activities that are sub-processes, the earliest **Child.CalcStartDate** is used.	Integer	
ExpectedFinish Date	The date the activity is expected to finish. For activities that are not sub-processes, the date equals to **ExpectedStartDate + CalcDuration 'ProcessInstance.Type.Calendar'** For activities that are sub-processes, the latest **Child.ExpectedFinishDate** is used.	Date	
ExpectedStart Date	The date the activity is expected to start. For activities that are not subprocesses, the date equals to **ProcessInstance.EpxectedStartDate + CalcStartDay 'ProcessInstance.Type.Calendar'**. For activities that are sub-processes, the earliest **Child.ExpectedStartDate** is used.	Date	
IncomingFlow List	Used to display a concatenated list of the prerequisites of this activity.	String	
OutlineLevel	The level of the activity, in terms of its relationship with other activities, in the process tree.	Quantity	
OutlineNumber	A string value used to indicate the activity's numerical position in the process instance hierarchy. For example, the first top-level activity has a value of 1, and activities underneath it have values such as 1.1., 1.2, and so on.	String	
OutgoingFlow List	Used to display a concatenated list of the subsequent activities of this activity.	String	
Parent	Parent sub-process of the activity. **Referenced table:** Activity	Reference	
SiblingIndex	An index number that is used to sort activities within a sub-process. Starts at 1 for each grouping of sibling activities.	Quantity	

Table 6.4: Activity (ProcOrch) fields

Field name	Description	Data type	Key
Status	The rolled up status of the activity. The status can be one of the following: • **NotStarted** • **InProgress** • **Finished** If the activity is not a sub-process, the status of the activity is based on the status of the users assigned to perform the activity: • **NotStarted**—the activity is NotStarted until at least one performer changes their status to InProgress or Finished. • **InProgress**—the activity is InProgress when at least one performer changes their status to InProgress or Finished. • **Finished**—the activity is Finished when all of the performers set their status to Finished. If the activity is not a sub-process, and has no assignments, the status is calculated in the following manner: • **NotStarted**—RunDate is less than the ExpectedStartDate • **InProgress**—The ExpectedStartDate is less than or equal to the RunDate, which is less than or equal to the ExpectedFinishDate • **Finished**—RunDate is greater than or equal to the ExpectedFinishDate If the activity is a sub-process, the status is based on the status of the child activities.	Enum	
Assignments	The set of users assigned to this activity.	Set	
Children	Set of sub-process records that reference this activity as a parent process.	Set	
IncomingFlows	Set of prerequisites for this activity.	Set	
Notifications	Set of notifications defined for this activity.	Set	
OutgoingFlows	Set of subsequent activities after this activity.	Set	
Parents	Set of sub-process records that reference this activity as a sub-process.	Set	

AggregatePartCustomer table

The **AggregatePartCustomer** table can be used to group part customers together to define the level at which forecast disaggregation occurs. In cases where it is sufficient to forecast at an aggregate level,

rather than down to a detailed part and customer combination, this can result in improved database performance.

This table ties unique part and customer combinations in the **PartCustomer** table with other **PartCustomer** records representing aggregate part or customer-based groupings. Therefore, each record in this table has two references to the **PartCustomer** table; the **Component** field which references the actual part and customer combination being aggregated, and the **Aggregate** field which references an aggregate part customer value.

For example, multiple customers for the same part might be associated with an aggregate part customer value representing the sales region in which all those customers are located. Thus, historical demands used as input in generating the statistical forecast can define the actual part and customer combination a demand was for, but it might only be necessary to disaggregate the part's statistical forecast to the regional level.

For more information about using this table, see "Define aggregate part customer relationships" on page 2091.

Note: In order for aggregate part-customer disaggregation to work, ensure the **PartCustomer.ForecastItem.Path** value for both the **Aggregate** and **Component** part customers are set to the same value.

Table 6.5: AggregatePartCustomer (Mfg) fields

Field name	Description	Data type	Key
Aggregate	A reference to an aggregate **PartCustomer** record. Aggregate part customers are used to group defined part and customer combinations together during forecast disaggregation. For example, this might reference a **PartCustomer** value added to aggregate all of a part's customers in a particular region. **Referenced table:** PartCustomer	Reference	
Component	A reference to a part and customer combination being aggregated under the **PartCustomer** value referenced in the **Aggregate** field. If this references the same value as the **Aggregate** field, then the component is assumed not to be aggregated (as of the **EffectiveInDate**). **Referenced table:** PartCustomer	Reference	Yes
EffectiveInDate	Date when the part customer aggregation defined on this record first becomes effective. For a given effective date, there should be at most one record for a particular Component (on a given date, a PartCustomer can only have one aggregate).	Date	

Table 6.5: AggregatePartCustomer (Mfg) fields

Field name	Description	Data type	Key
Id	A unique string identifier for this record. It is recommended to set this to a string returning the EffectiveInDate field value (in other words, `text (EffectiveInDate, yyyymmdd)`. This ensures that additional records having the same Component and EffectiveInDate value are flagged and rejected as duplicates.	String	Yes
Type	A reference to a control setting used to include or exclude aggregate part customers from use in disaggregation calculations. **Referenced table:** AggregatePartCustomerType	Reference	

AggregatePartCustomer table – calculated and set fields

The following describes the calculated and set fields in the **AggregatePartCustomer** table. For an introduction to this table, and descriptions of its input fields, see "AggregatePartCustomer table" on page 179.

Table 6.6: Calculated AggregatePartCustomer (Mfg) fields

Field name	Description	Data type	Key
EffectiveOut Date	Date when the part customer aggregation defined on this record stops being effective. Each record is considered effective until the next **EffectiveInDate** on a record with matching **Aggregate** and **Component** values (a value of "Future" is reported if no such record exists).	Date	
IsNested	Indicates whether this is a nested record. A nested record refers to situations where the value referenced in the **Aggregate** field is also referenced in the **Component** field of another **AggregatePartCustomer** record. Valid values are: • **N**—a nested record that is ignored during forecast disaggregation calculations. • **Y**—a valid record that is used during forecast disaggregation calculations.	Boolean	

Allocation table

This table identifies allocations; that is, dependent demand items generated because a work order (scheduled receipt) was created for a make item. It only contains those allocations which were contained in your enterprise data source, and imported into the RapidResponse data model. Typically, this is done at a time close to when the order is being released to the shop floor, or when you have deviated from the standard bill of materials. For any scheduled receipts you are providing allocations to RapidResponse for, you need to ensure it does not generate allocations for them. This is done by setting an appropriate value for the Status field on the ScheduledReceipt table (this is a reference to the **SupplyStatus** table).

If you do not provide allocations, RapidResponse will generate them and store them in the NewAllocation table. For more information about this table, see "NewAllocation table" on page 1137.

Table 6.7: Allocation (Mfg) fields

Field name	Description	Data type	Key
BaseKey	Can optionally be used to uniquely identify each Allocation record. **Note:** If you have upgraded to Version 2015.3 and enabled record uniqueness on this table prior to the upgrade, this field is a key field. For more information, see "Key fields" on page 141.	String	
DueDate	The date the part is required during the assembly process (not the supply's DueDate). **Default value**: Future	Date	
Model	The assembly model the allocation is associated with. For example, this might be different than the scheduled receipt model in cases where Order BOM logic is used. If left Null, then depending on configuration either the model specified in the **InputModel** field on the **ScheduledReceipt** record or the default model is used. **Referenced table:** Model (Nullable) **Note:** This field was added in Version 2016.2.	Reference	
Operation	The specific operation in the scheduled receipt's routing where this component part is used. The referenced operation can be in the routing's standard sequence or one of its parallel sequences. Note that this reference is only considered if the parent supply uses capacity-based variable lead time (**OrderPolicy.UseVarLeadTime** set to "CRP"). **Referenced table:** CRPOperation (Nullable) **Reference Syntax**: Operation.Id, Operation.Sequence.Id, Operation.Sequence.Routing.Id, Operation.Sequence.Routing.Site.	Reference	

Table 6.7: Allocation (Mfg) fields

Field name	Description	Data type	Key
Part	The part required for the manufacturing order. **Referenced table:** Part **Reference Syntax:** Part.Name, Part.Site **Note:** If you have upgraded to Version 2015.3 and enabled record uniqueness on this table prior to the upgrade, this field is a key field. For more information, see "Key fields" on page 141.	Reference	
QuantityPer	The flat quantity per between the scheduled receipt part and the allocation part. This should include any consideration for BOM scrap. For example, if the QuantityPer on the BOM record is 2 and Scrap is 20%, this field should be set to 2.4. This field should be populated for all substitutable allocations underneath a given scheduled receipt, and indicates the number of units of the allocation part required to build one unit of the scheduled receipt part. QuantityPer is used in calculating the InKit value, as well as in rolling up availability of the allocation for determining incremental availability of the scheduled receipt. For records that do not define substitutable allocations, this field can be ignored as RapidResponse calculates an effective quantity per based on the ratio between the allocation and the scheduled receipt. **Default value**: 0 For more information, see "Substitutable allocations" on page 1576.	Quantity	
Remaining Quantity	The amount that is still needed from inventory. **Default value**: 0	Quantity	
Scheduled Receipt	The scheduled receipt for which this allocation is reserved. **Referenced table:** ScheduledReceipt **Reference Syntax:** ScheduledReceipt.Line, ScheduledReceipt.Order.Type, ScheduledReceipt.Order.ID, ScheduledReceipt.Order.Site **Note:** If you have upgraded to Version 2015.3 and enabled record uniqueness on this table prior to the upgrade, this field is a key field. For more information, see "Key fields" on page 141.	Reference	
Shop	The shop floor location associated with this Allocation record. **Referenced table**: Shop (this reference is nullable in new installations of RapidResponse Version 10.1 and later).	Reference	

Table 6.7: Allocation (Mfg) fields

Field name	Description	Data type	Key
StartUnit	The unit number for the first item being made from this allocated material. **Default value**: -1	Integer	
SubstituteGroup	A reference to the **SubstituteGroup** table that is used to define groups of substitutable allocations underneath a scheduled receipt. All allocations that are assumed to be substitutable for one another underneath a given scheduled receipt must point to the same SubstituteGroup record. If the referenced SubstituteGroup record has a **SubstituteGroupType.ProcessingRule** value of "Substitute", then the availability of each substitutable allocation can be individually rolled up to the scheduled receipt. This allows for incremental availability on the scheduled receipt to be calculated based on when each substitute component supply is available. InKit calculations are also affected by substitutable allocations. **Referenced table**: SubstituteGroup For more information about using this field, see "Substitutable allocations" on page 1576.	Reference	
TotalQuantity	The amount that was needed. **Default value**: 0	Quantity	

Allocation table – calculated and set fields

The following describes the calculated and set fields in the Allocation table. For an introduction to this table, and descriptions of its input fields, see "Allocation table" on page 182.

Table 6.8: Calculated Allocation(Mfg) fields

Field name	Description	Data type	Key
EarliestExpiry Date	The earliest date that supply can expire if it is to be used in satisfying this demand. The value in this field depends on the expiry related settings for both the assembly on the referenced **ScheduledReceipt** record and the component being reserved by this allocation. It is calculated as follows: • If the assembly on the scheduled receipt has a **Type.ExpiryRule** of "Dependent", then this field inherits the **EarliestExpiryDate** from the scheduled receipt. • If the assembly on the scheduled receipt has a **Type.ExpiryRule** of "Self", then this field is calculated starting from the **DueDate** on this allocation and adding the assembly's **Part.MinimumShelfLife** value (in units of the assembly's **ExpiryCalendar**). • If the assembly on the scheduled receipt has a **Type.ExpiryRule** of "SelfReset", then this field is calculated starting from the **DueDate** on this allocation and adding the component's **Part.MinimumShelfLife** value (in units of the component's **ExpiryCalendar**).	Date	
EffQuantity	The effective quantity of this dependent demand. It equals the RemainingQuantity unless ScheduledReceipt.OriginalQuantity > 0. The EffQuantity is calculated to account for the new ScheduledReceipt.Quantity. Typically, assuming valid data, the value in this field should be greater than zero. A negative quantity in this field might be indicative of a bad data environment. For example, if using RapidResponse's method of automatically updating the allocation every time there is a change in the scheduled receipt, this might happen if the Quantity on the scheduled receipt was changed without also changing the OriginalQuantity on the scheduled receipt. **Note:** For information about how this field is calculated, see "Automatic allocation adjustment" on page 1399.	Quantity	
FlowToCommon ForecastQuantity	The quantity of this order that consumed forecast. from the common forecast pool (that is, because all of the customer's forecast had already been consumed).	Quantity	
ForecastQuantity	The quantity of this order that consumed forecast. This includes both forecast consumed from the customer's forecast and forecast consumed from the common pool forecast.	Quantity	

Table 6.8: Calculated Allocation(Mfg) fields

Field name	Description	Data type	Key
InKit	The quantity of this allocation that remains in the allocation kit, but not yet allocated to completed supply units. This field is calculated as follows: `MAX (0, Allocation.TotalQuantity - Allocation.RemainingQuantity - ((ScheduledReceipt.TotalQuantity - ScheduledReceipt.Quantity) * EffQtyPer)` where `EffQtyPer` is calculated based on the ratio between the allocation and the scheduled receipt, unless the record represents a substitutable allocation in which case it is set to the input QuantityPer value on the Allocation record. If the record represents a substitutable allocation, the formula shown above is individually applied to each substitutable allocation under a scheduled receipt, starting with the allocation with the lowest RemainingQuantity, until the finished amount on the receipt has been fully distributed and consumed.	Quantity	
IsRecursive	Indicates whether recursive data has been found during processing. Bill records that have a BOMType.EffectivityRule value of 'Never' are ignored. Valid values are: • **Y**—recursive data has been found. The calculation skips the parts involved in the recursive relationship. • **N**—recursive data has not been found. **Note:** A self-allocation occurs when the part on the **Allocation** record is the same as the part on the referenced **ScheduledReceipt** record. This is an allowable form of recursion (returns "N") and represents a rework order where some assembly is being returned for rework.	Boolean	
MappedPool	The pool used in netting this demand. **Referenced table:** Pool	Reference	
ReschedDate	The date RapidResponse recommends the allocation should be due in order to satisfy the parent scheduled receipt. For example, this might differ from the provided DueDate based on rescheduling of the receipt. If the allocation is for a backflush scheduled receipt (for example, where SupplyStatus.State = 'BackflushAndAllocated'), this value is always set to 'Past'. If the allocation is for a scheduled receipt not processed by Netting, this is value is always set to 'Undefined'.	Date	
Unsatisfied Quantity	The portion of this demand that was left unsatisfied. This field is only applicable to allocations on scheduled receipts using transfer part sources.	Quantity	

AllotmentOverride table

This table holds allotment overrides which are used to manually reserve limited component supply to the higher level demands or supplies that require them. Typically, when faced with limited component supply, RapidResponse performs allotments based on things like due date, demand priority and fair or equal share logic. However, in some cases the desired allotment of limited supply cannot easily be achieved through RapidResponse processing rules and settings. In these cases, allotment overrides can be used to override the supply allotments RapidResponse would otherwise make and manually share or reserve components to help achieve the desired availability of top-level demands.

The **AllotmentOverride** table identifies and controls processing of each unique allotment override in RapidResponse. The specifics of each allotment override are then specified in the **AllotmentOverrideDetail** table which references the **AllotmentOverride** table and contains details such as the component the allotment override pertains to, as well as the amount of that component's supply to be reserved. Multiple AllotmentOverrideDetail records can point to a single AllotmentOverride values in cases where multiple components are being reserved together.

The supply reserved through a given AllotmentOverride and its associated AllotmentOverrideDetail record(s) is then ultimately allocated to those higher level demands or supplies which reference that AllotmentOverride value. The following tables have a reference to the AllotmentOverride table for this purposes:

- **IndependentDemand**—for reserving component supply to specific top-level demands.
- **ScheduledReceipt**—for reserving component supply to specific work orders.
- **PartCustomerTimePhasedAttributes**—for reserving component supply to S&OP consensus forecast demands for a given part and customer combination.
- **PartSource**—for reserving component supply to dependent demands with supply generated from a given part source.

Note: This table is primarily intended to be populated using the Allotment Overrides workbook. If necessary, however, values can be imported into this table. For more information about allotment overrides, see "Allotment overrides" on page 1853.

Table 6.9: AllotmentOverride (Mfg) fields

Field name	Description	Data type	Key
Description	A description of this allotment override.	String	
Id	A unique string identifier for this allotment override record. For example, an Id might combine the Customer and Site the component supply is being reserved for. **Note:** If the record is created using the AllotmentOverride workbook, this Id set to a string determined by the selected Allotment Override Id Template.	String	Yes

Table 6.9: AllotmentOverride (Mfg) fields

Field name	Description	Data type	Key
Sequence	A number that can be used to set the processing order when there are multiple allotment overrides reserving supply of the same component part (records with lower values are given priority). For example, if there are multiple AllotmentOverride records reserving a given component's supply to different demands, and there is not actually enough of the reserved component to full satisfy all those demands on time, RapidResponse attempts to satisfy demands referencing AllotmentOverride record with the lowest Sequence values first.	Integer	
Type	A reference that sets processing rules for this allotment override. For example, it determines if this record and its associated details are enabled or disabled in analytic calculations. **Referenced table:** AllotmentOverrideType	Reference	

AllotmentOverride table – calculated and set fields

The following describes the calculated and set fields in the AllotmentOverride table. For an introduction to this table, and descriptions of its input fields, see "AllotmentOverride table" on page 187.

Table 6.10: AllotmentOverride calculated (Mfg) fields

Field name	Description	Data type	Key
Allotment OverrideDetails	Set of AllotmentOverrrideDetails records that contain details of reserved component supply associated with this allotment override.	Set	
Independent Demands	Set of IndependentDemand records that are reserving component supply from this allotment override.	Set	
PartCustomer TimePhased Attributes	Set of PartCustomerCustomerTimePhasedAttributes records that are reserving component supply from this allotment override.	Set	
PartSources	Set of PartSource records that are reserving component supply from this allotment override.	Set	
Scheduled Receipts	Set of ScheduledReceipt records that are reserving component supply from this allotment override.	Set	

AllotmentOverrideDetail table

The **AllotmentOverrideDetail** table contains details of allotment overrides. These are used in cases where there is both limited component supply and a need to override the supply allocations calculated by RapidResponse in order to achieve the desired component distribution and availability on higher level demands or supplies. For example, this table specifies the component whose supply is to be reserved along with the amount of supply to be reserved. Each record in this table also contains a reference to **AllotmentOverride** table which is used to identify each allotment override in RapidResponse and ties the component supply identified in this table to the top-level demands or supplies where they are to be allocated.

Although this tables allows for a specified quantity of a component to be reserved to the demands or supplies associated with the referenced allotment override, it does not provide the ability to choose the specific supply that will provide the reserved quantity.

Note: For more information about allotment overrides, see "Allotment overrides" on page 1853. RapidResponse also includes the **AllotmentOverrides** workbook to simplify the process of creating and maintain allotment overrides. For more information about this workbook see the *RapidResponse Applications Guide*.

Table 6.11: AllotmentOverrideDetail (Mfg) fields

Field name	Description	Data type	Key
Allotment Override	A reference to the AllotmentOverride value the details in this record pertain to. Supply reserved by this detail record can be used by demands or supplies that point to the referenced AllotmentOverride value (for example, from an IndependentDemand record). **Referenced table:** AllotmentOverride	Reference	Yes
Component	A reference to the component part whose supply is being reserved for the allotment override. The component can be multiple levels down the product structure from the assembly part the supply is reserved for. For example, supply of a bottom level component might be reserved to demand from a top level assembly. In these cases, RapidResponse ensures the allotment override details are propagated up the product structure so that the component supply is ultimately used in satisfying the assembly demand. **Referenced table:** Part	Reference	Yes

Table 6.11: AllotmentOverrideDetail (Mfg) fields

Field name	Description	Data type	Key
Date	The allotment override date for the component. In order to find component supply to reserve for the allotment override, RapidResponse starts looking on this date, and then moves back through earlier date buckets as required. If sufficient supply can still not be found, RapidResponse will then look in buckets after this date. If multiple supplies on a given date are available to provide the reservation, RapidResponse will choose which one to use (that is, you cannot specify the specific order to provide the quantity). Also, when **AllotmentOverride.Type** is set to "AfterRunDate", the date provided here sets when this record is effective in RapidResponse analytic calculations (effective as long as this date is on or after RunDate). For more information, see "AllotmentOverrideType table" on page 671.	Date	
Description	A description of this allotment override detail.	String	
Id	An optional string identifier. This field is used to uniquely identify records in cases where a given Component and AllotmentOverride combination have multiple detail records (that is, with different date values). Typically, this might be set to a string displaying the date associated with the record. Otherwise, if there is only one detail record for a given Component and AllotmentOverride combination, this field can be left blank.	String	Yes
Quantity	The amount of the component part supply to be reserved for the allotment override. If the amount specified is more than is actually required by the demands or supplies associated with the allotment override, the difference is subsequently made available to other demands and supplies.	Quantity	

AlternatePart table

This table is used to define interchangeable and substitute part relationships. Each record identifies a PrimaryPart and a SubstitutePart, and the setting in the Type field indicates if the parts are interchangeable or substitutes.

In an interchangeable part relationship, all parts are considered equivalent in form, fit, and function. Demand for one part in an interchangeable part group can be satisfied by supply from any of the other parts in the group, and no preference is given as to which part's supply satisfies the demand. Also, planned orders and calculated results are only generated for the primary part in an interchangeable part group. For more information about interchangeable parts, see "Interchangeable parts" on page 1545.

In a substitute part relationship, a substitute part can be used in a place of the primary part, but the primary part cannot be used in place of a substitute part. Substitute parts are only used when not

enough of the primary part can be found. Also, planned orders and calculated results can be generated for both the primary and substitute part(s) in a substitute part relationship. For more information about substitute parts, see "Global part substitution" on page 1551.

Table 6.12: AlternatePart (Mfg) fields

Field name	Description	Data type	Key
BaseKey	Along with the PrimaryPart and SubstitutePart fields, uniquely identifies the interchangeable or substitute part grouping. This field might contain, for example, a manufacturer name, the name of a group of parts, or a blank value.	String	Yes
EffectiveInDate	Date on which this AlternatePart record becomes effective. Along with EffectiveOutDate and the setting in Type.EffectivityRule, this field defines the period over which this record is effective. Only applicable to substitute part relationships (interchangeable part relationships are always considered effective).	Date	
EffectiveOutDate	Date on which this AlternatePart record is no longer effective. Along with EffectiveInDate and the setting in Type.EffectivityRule, this field defines the period over which this record is effective. Only applicable to substitute part relationships (interchangeable parts relationships are always considered effective).	Date	
Pool	For substitute part relationships, defines the applicable pool. Pools are used to enable customer-specific part substitution. **Referenced table:** Pool	Reference	
PrimaryPart	The part that either interchangeable or substitute parts are defined for. **Referenced table**: Part	Reference	Yes

Table 6.12: AlternatePart (Mfg) fields

Field name	Description	Data type	Key
Sequence	For substitute part relationships, this value is used to define a preference between eligible substitute parts with lower values being used first. This value is also compared against the **PrimarySubstitutionSequence** value on the primary Part record to determine if existing supply on a given substitute or the primary part is preferred. If this value is greater than or equal to the value in **PrimarySubstitutionSequence**, then existing supply on the primary part is preferred. However, if this value is strictly less than the value in **PrimarySubstitutionSequence**, then existing supply of this substitute is used before that of the primary (and in such cases, new planned orders will never be generated on the substitute to satisfy demand from the primary part). If multiple parts have the same Sequence value, then the following sort order is used to determine which substitutes are used first: • Pool specific records. • FirstEffectiveDate (earliest). • SubstitutePart.Name and SubstitutePart.Site (alphabetical) **NOTE**: If using global part substitution along with multi-level search logic, then some multi-level criteria take precedence over the Sequence value when determining which substitute parts are used. For example, if two substitutes can satisfy a demand equally well and the lowest level of component supply used by each comes from input supply, then preference is given to the substitute that provides that supply at a higher level of the product. That is, substitutes with shorter paths to component materials are preferred even if they do not have the lower Sequence value.	Integer	
SubstitutePart	That part that can be used either interchangeably or as a substitute for the primary part. **Referenced table**: Part	Reference	Yes
Type	A reference that determines if this record represents a substitute or interchangeable part relationship. If it is a substitute part relationship, then this reference includes other rules that affect substitution calculations. **Referenced table**: AlternatePartType	Reference	

AlternatePart table – calculated and set fields

The following describes the calculated and set fields in the AlternatePart table. For an introduction to this table, and descriptions of its input fields, see "AlternatePart table" on page 190.

Table 6.13: AlternatePart calculated (Mfg) fields

Field name	Description	Data type	Key
FirstEffectiveDate	The date when this AlternatePart record first becomes effective. Represents an adjusted EffectiveInDate that takes Type.EffectivityRule into account.	Date	
IsRecursive	Indicates whether this pair of parts is recursive, or if the parts create a recursive product structure. A pair is recursive if both parts are primary parts in a group, and both are substitutes of each other. For example, if Part A is a substitute for Part B and Part B is a substitute for Part A, the pair is recursive. A product structure is recursive if a part is a component of itself. For example, assume you have a product structure for Part A, with component Part C, which has component Part B. Part A is interchangeable with Part B, which means Part A is a component of itself, and the product structure is recursive. Recursive pairs and product structures are not valid, and are ignored when interchangeable and substitute part relationships are considered. Valid values are: • **Y**—The pair is recursive. • **N**—The pair is not recursive.	Boolean	
LastEffectiveDate	The final date when this AlternatePart record is effective. Represents an adjusted EffectiveOutDate that takes Type.EffectivityRule into account.	Date	

AlternateRouting table

The **AlternateRouting** table is used as a place holder for alternate routings. It links routings to parts for a list of alternate routings. To use an alternate routing, the Routing field on the Part table must be changed to one of the alternate routings listed here.

Table 6.14: AlternateRouting (Mfg) fields

Field name	Description	Data type	Key
Part	The name of the part. **Referenced table:** Part	Reference	
Routing	The routing Id. **Referenced table:** Routing	Reference	

Assignment table

The assignment table links the RapidResponse users to the activities that they are tasked with performing. It defines information such as the date when the user begins work on an activity and the user's assignment status.

Table 6.15: Assignment (ProcOrch) fields

Field name	Description	Data type	Key
Activity	The activity associated with this assignment. **Referenced table:** Activity	Reference	
FinishDate	The date the assignment is complete. An assignment is complete when a user changes their assignment status to Finished.	Date	
Id	A unique id that identifies this assignment.	String	Yes
StartDate	The date work on the assignment starts. An assignment is started when a user changes their assignment status to InProgress or Finished.	Date	
Status	The status of the assignment. Valid values are: • **NotStarted** • **InProgress** • **Finished**	Enum	
UserId	The RapidResponse user ID of the user linked to this of this assignment.	String	

Assignment table – calculated and set fields

The following describes the calculated and set fields in the Assignment table. For an introduction to this table, and descriptions of its input fields, see "Assignment table" on page 194.

Table 6.16: Assignment (ProcOrch) fields

Field name	Description	Data type	Key
ActualFinishDate	If the **Status** is "Finished" and **FinishDate** is defined, then the later of the **FinishDate** or **ActualStartDate** is used. If the **Status** is "Finished" but **FinishDate** is undefined, then the later of the the **ExpectedFinishDate** on the activity or **ActualStartDate** is used.	Date	
ActualStartDate	If the **Status** is "Started" or "Finished", then the **StartDate** is used. If the **Status** is "Started" or "Finished", but no **StartDate** is defined, then the **ExpectedStartDate** of the activity is used.	Date	

Assumption table

This table contains details of external information or "assumptions" on which your S&OP plans are based. For example, an assumption from the marketing group might note an expected change in market share for a particular product line.

The Assumption table supports Sales and Operations Planning in RapidResponse. Values in this table are added and maintained using the **New Assumption** and **Edit Assumption** dialog boxes in RapidResponse. These dialog boxes can only be used in workbooks compatible with the PartCustomer, Part, PartSource, and Constraint tables. For more information about assumptions, see the *RapidResponse Applications Guide*.

Table 6.17: Assumption (Mfg) fields

Field name	Description	Data type	Key
AssignTo	The User ID of the user the assumption is assigned to in RapidResponse. This is the user who is expected to take some action on this assumption (for example, to review it).	String	
Created	The date and time at which this assumption record was created.	DateTime	
Creator	The User ID of the user who created the assumption in RapidResponse.	String	
DueDate	The date that any tasks associated with this assumption should be completed by.	Date	
EffectiveIn	The date on which this assumption become effective.	Date	
EffectiveOut	The date on which this assumption is assumed to no longer be effective.	Date	

Table 6.17: Assumption (Mfg) fields

Field name	Description	Data type	Key
Id	A unique identifier for this assumption.	String	Yes
LastModified	The date and time at which this assumption record was last modified.	DateTime	
Status	A reference to the current status of this assumption. For example, an assumption status might be "open", "closed" or "invalid". **Referenced table:** AssumptionStatus	Reference	
Target	A reference that identifies the active hierarchy and filter settings in the workbook at the time this assumption record was created. **Referenced table:** ReferenceForecastTarget	Reference	
Text	A description of the assumption.	String	
Type	A reference to the type value used to categorize this assumption. For example, type values might be used to indicate the department in your company which the assumption is associated with. **Referenced table**: AssumptionType	Reference	

Assumption table – calculated and set fields

The following describes the calculated and set fields in the Assumption table. For an introduction to this table, and descriptions of its input fields, see "Assumption table" on page 195.

Table 6.18: Calculated Assumption (Mfg) fields

Field name	Description	Data type	Key
AssumptionBy Constraints	The set of AssumptionByConstraint records associated with this assumption.	Set	
AssumptionByParts	The set of AssumptionByPart records associated with this assumption.	Set	
AssumptionBy PartCustomers	The set of AssumptionByPartCustomer records associated with this assumption.	Set	
AssumptionBy PartSources	The set of AssumptionByPartSource records associated with this assumption.	Set	

AssumptionByConstraint table

This table associates assumptions with the constraints they apply to. A given Assumption record can apply to many constraints, and one Constraint record can have many assumptions associated with it.

The **AssumptionByConstraint** table supports Sales and Operations Planning in RapidResponse. Values in this table are added and maintained using the **New Assumption** and **Edit Assumption** dialog boxes. These dialog boxes might be available from select RapidResponse workbooks that are compatible with Constraint-based filters and include hierarchies. For more information about assumptions, see the *RapidResponse Applications Guide*.

Table 6.19: AssumptionByConstraint (Mfg) fields

Field name	Description	Data type	Key
Assumption	A reference to the assumption belonging to this assumption and constraint combination. **Referenced table:** Assumption	Reference	Yes
Constraint	A reference to the constraint belonging to this assumption and constraint combination. **Referenced table:** Constraint	Reference	Yes

AssumptionByPart table

This table associates assumptions with the parts they apply to. A given Assumption record can apply to many parts, and one Part record can have many assumptions associated with it.

The **AssumptionByPart** table supports Sales and Operations Planning in RapidResponse. Values in this table are added and maintained using the **New Assumption** and **Edit Assumption** dialog boxes. These dialog boxes might be available from select RapidResponse workbooks that are compatible with Part-based filters and include hierarchies. For more information about assumptions, see the *RapidResponse Applications Guide*.

Table 6.20: AssumptionByPart (Mfg) fields

Field name	Description	Data type	Key
Assumption	A reference to the assumption belonging to this assumption and part combination. **Referenced table:** Assumption	Reference	Yes
Part	A reference to the part belonging to this assumption and part combination. **Referenced table:** Part	Reference	Yes

AssumptionByPartCustomer table

This table associates assumptions with the part customers they apply to. A given Assumption record can apply to many part customers, and one PartCustomer record can have many assumptions associated with it.

The **AssumptionByPartCustomer** table supports Sales and Operations Planning in RapidResponse. Values in this table are added and maintained using the **New Assumption** and **Edit Assumption** dialog boxes. These dialog boxes might be available from select RapidResponse workbooks that are compatible with PartCustomer-based filters and include hierarchies. For more information about assumptions, see the *RapidResponse Applications Guide*.

Table 6.21: AssumptionByPartCustomer (Mfg) fields

Field name	Description	Data type	Key
Assumption	A reference to the assumption belonging to this assumption and part customer combination. **Referenced table:** Assumption	Reference	Yes
PartCustomer	A reference to the part customer belonging to this assumption and part customer combination. **Referenced table:** PartCustomer	Reference	Yes

AssumptionByPartSource table

This table associates assumptions with the part sources they apply to. A given Assumption record can apply to many part sources, and one PartSource record can have many assumptions associated with it.

The **AssumptionByPartSource** table supports Sales and Operations Planning in RapidResponse. Values in this table are added and maintained using the **New Assumption** and **Edit Assumption** dialog boxes. These dialog boxes might be available from select RapidResponse workbooks that are compatible with PartSource-based filters and include hierarchies. For more information about assumptions, see the *RapidResponse Applications Guide*.

Table 6.22: AssumptionByPartSource (Mfg) fields

Field name	Description	Data type	Key
Assumption	A reference to the assumption belonging to this assumption and part source combination. **Referenced table:** Assumption	Reference	Yes
PartSource	A reference to the part source belonging to this assumption and part source combination. **Referenced table:** PartSource	Reference	Yes

AssumptionStatus table

This table contains all valid status values defined in your company to indicate the state of an assumption. For example, status values might indicate if an assumption is open or closed.

The AssumptionStatus table supports Sales and Operations Planning in RapidResponse. This table should be configured during initial RapidResponse deployment.

Table 6.23: AssumptionStatus (Mfg) fields

Field name	Description	Data type	Key
Description	A description of this assumption status.	String	
Value	A name for this assumption status. Examples of assumption status value might include “Open”, “Closed”, and “Under Review”. This field is referenced from the Status field on the Assumption table.	String	Yes

AssumptionStatus table – calculated and set fields

The following describes the calculated and set fields in the AssumptionStatus table. For an introduction to this table, and descriptions of its input fields, see "AssumptionStatus table" on page 199. This table should be configured during initial RapidResponse deployment

Table 6.24: Calculated AssumptionStatus (Mfg) fields

Field name	Description	Data type	Key
Assumptions	The set of Assumption records associated with this assumption status.	Set	

AssumptionType table

This table contains all valid type values defined in your company to categorize assumptions. For example, type values might indicate the department in your company that the assumption is associated with.

This AssumptionType table should be configured during initial RapidResponse deployment.

Table 6.25: AssumptionType (Mfg) fields

Field name	Description	Data type	Key
Description	A description of this assumption type.	String	
Value	A unique identifier (name) for this assumption type. Examples of assumption status value might include "Revenue", or "Action". This field is referenced from the Type field on the Assumption table.	String	Yes

AssumptionType table – calculated and set fields

The following describes the calculated and set fields in the AssumptionType table. For an introduction to this table, and descriptions of its input fields, see "AssumptionType table" on page 199.

Table 6.26: Calculated AssumptionType (Mfg) fields

Field name	Description	Data type	Key
Assumptions	The set of Assumption records associated with this assumption type.	Set	

AttributeMap table

The **AttributeMap** table holds attribute rules that pair named attributes and their values together for use with certain analytic calculations. Attributes are custom data model elements that identify specific characteristics of demands and/or supplies and rely on calculated field expressions to identify those data characteristics in a particular table.

Attributes rules can be used to provide finer control over any or all of the following calculations in RapidResponse:

- **Supply Allotment**— used to ensure that demands with given attribute values can only be satisfied by supplies that have attribute values meeting specified criteria. For example, demands from a given part customer might only be able to accept supply of the part if was assembled at a particular location or contains components produced by select suppliers.
- **Forecast consumption**—used to ensure that forecasted demands can only be consumed by actual demands with matching attribute values. For example, a forecast demand associated with a particular customer or region might only be eligible to be consumed by actual demands from that same customer or region.
- **Forecast adjustments**—used to ensure that forecast adjustments and overrides with attributes specified on them are only made against consensus forecast records with matching attributes. For example, demand attributes might be used to adjust consensus forecast values for a particular customer (this adjustment might later influence supply selection if the same attribute is defined for supply allotments).

For each rule in this table, the **FromAttributeName** and **FromAttributeValue** fields must be used to specify a demand-based attribute and a value to associate with it, the **ToAttributeName** and

ToAttributeValue fields can be used specify a supply-based attribute and one or values to associate with it (if applicable).

The **AttributeMap** table is not shown in the *RapidResponse Data Model for Import* poster. Values are typically added to this table using the standard Attribute Rules workbook included with RapidResponse. For example, different attribute values might be specified in different scenarios using this workbook as part of a simulation exercise. By default, the Attribute Rules workbook is available only to data administrators, but it might be shared to other users as required. For more information about this workbook, see the *RapidResponse Applications Guide*.

Table 6.27: AttributeMap (Core) fields

Field name	Description	Data type	Key
BaseKey	A string value used to uniquely identify each AttributeMap record.	String	Yes
Enabled	Specifies if the attribute rule defined by this record is used by RapidResponse analytics: • **N**—this rule is ignored by analytic calculations. • **Y**—this rule is eligible to be used by analytic calculations (usage further depends on the Type setting). **Default value**: N	Boolean	
FromAttribute Name	The name of a demand attribute to use with this rule. For example, this might refer to an attribute that identifies customers or part and customer combinations. It is recommended to specify attribute names in their fully namespace qualified format (that is, namespaceName::attributeName) to avoid potential issues if the same attribute name is ever defined in multiple namespaces.	String	

Table 6.27: AttributeMap (Core) fields

Field name	Description	Data type	Key
FromAttribute Value	A single value to associate with the demand attribute specified for this rule. For example, if the attribute specified in the FromAttributeName field identifies customers, then this field might contain the name of a particular customer that has some attribute-based qualifications or limitations on the supplies it will accept. Note that this is a string field, however the values provided should resolve to the data type of the demand attribute itself. Depending on the data type of the attribute identified in the FromAttributeName field, the following should be kept in mind: • **Boolean**—only Y (yes) and N (no) values are permitted. • **Date**—dates can be specified in any of the date formats supported in RapidResponse (Past, Future, Today and MRPDate keywords can also be used). • **Integer / Quantity**—numeric values can be specified with or without leading plus (+) or minus (-) signs, and optional decimal point (quantities only). • **String**—string values can be specified directly or enclosed in matching single, double, or start/end quotes. To escape a character in a string, use the backslash character (for example, 'AB\'C').	String	
ToAttribute Name	The name of the supply attribute, to use in this rule. For example, this might refer to an attribute used to identify plant locations or component suppliers. It is recommended to specify attribute names in their fully namespace qualified format (that is, namespaceName::attributeName) to avoid potential issues if the same attribute name is defined in multiple namespaces. **Note:** If this rule is only being used for forecast consumption and/or adjustment but not supply allotment (that is, has **Type.SupplySelection** set to "N"), then any valid attribute name can be specified here. For example, the name of the demand attribute might be used. In such cases, the **ToAttributeValue** field can then be left blank.	String	

Table 6.27: AttributeMap (Core) fields

Field name	Description	Data type	Key
ToAttribute Value	One or more values to associate with the supply attribute, if any, specified for this rule. For example, if the attribute specified in the ToAttributeName field identifies component suppliers, then this field might contain a delimited list of all qualified suppliers whose components can be used in end-items provided to a particular part customer. Note that this is a string field, however the values provided should resolve to the data type of the supply attribute itself and can also include certain elements of the search syntax used in RapidResponse worksheets as follows: • **Boolean**—only Y (yes) and N (no) values are permitted. • **Date**—dates can be specified in any of the date formats supported in RapidResponse (Today and MRPDate keywords are not supported). Greater than (>, >=) and less than (<, <=) symbols can be used to indicate values before or after a given date, and two dots can be used to indicate a date range (for example, 20120801..20120831). • **Integer / Quantity**—numeric values can be specified with or without leading plus (+) or minus (-) signs, and can include an optional decimal point (quantities only). Greater than (>, >=) and less than (<, <=) symbols can be used to indicate values above or below a specified value, and two dots can be used to indicate a quantity range (for example, 500..2000). • **String**—string values can be specified directly or enclosed in matching single, double, or start/end quotes. A list of string values can be specified by using a comma separator (for example, 'AB', 'CD', 'XYZ') and any value within the list will then be considered an attribute match. To indicate a match occurs only if the specified attribute values are not found, use <> (for example, <> ABC). To escape a character in a string, use the backslash character (for example, 'XY\'Z').	String	
Type	A reference to the type value that defines how the attribute rule defined on this record is interpreted and used. Based on the settings defined on the referenced type, the attribute rule might be used during supply allotment, forecast consumption, and/or forecast adjustment calculations. **Referenced table:** AttributeMapType	Reference	

Table 6.27: AttributeMap (Core) fields

Field name	Description	Data type	Key
Weight	If this attribute rule is to be used in supply allotment calculations, then this field can be used to specify and assign a weight to demands that have values matching those defined in the FromAttributeValue field. This weight is then used as part of the criteria in determining the order in which demands are processed and hence the order in which they receive potentially scarce supplies. For example, it can be used to ensure the demands associated with specified demand attribute values, such as a customer, are given priority over others. RapidResponse also automatically calculates a weight for each record which is applied to matching demands when this field is set to 0 (zero). This is the default behavior and ensures that a higher weight is assigned to records that are likely to have fewer attribute matches, and a lower weight is assigned to records that are likely to have more attribute matches. For example, an attribute rule that defines a single acceptable supply source would be assigned a higher weight than a rule that defines lists of acceptable suppliers. **Default value**: 0 **Note:** For more information about how weights are calculated and used, see "Attribute weights" on page 1827.	Quantity	

AttributeMap table – calculated and set fields

The following describes the calculated and set fields in the AttributeMap table. For an introduction to this table, and descriptions of its input fields, see "AttributeMap table" on page 200.

Table 6.28: Calculated AttributeMap (Core) fields

Field name	Description	Data type	Key
ErrorMessage	If a record has its **Enabled** field set to "Y", this field returns a string indicating any errors in the map definition. For example, an attribute name might be misspelled or the value provided for an attribute might be incompatible with its data type. An attribute rule will not be used in analytic calculations until all reported errors have been fixed.	String	

BaselineConflict table

The **BaselineConflict** table contains details of task scheduling conflicts that existed at the point when a project was baselined (copied to the baseline scenario). Task conflicts can occur if a constraint or material order link causes a task to move in the opposite direction from which its project is being scheduled in such a manner that not all parameters or limits placed on the task can be simultaneously

respected. Each record in this table identifies the task and baselined project in which the conflict existed along with details of the constraint or material order requirement that caused the conflict.

For details of actual task conflicts in projects, see "Conflict table" on page 963.

Table 6.29: BaselineConflict (ProjMgmt) fields

Field name	Description	Data type	Key
Constraint	If the conflict in the baselined project was caused by a task constraint, this indicates the type of constraint (for example, "FinishNoEarlierThan").	String (Enum)	
Date	The date associated with the source of the task conflict in the baseline project. If the conflict was caused by a task constraint, then the constraint date is reported. Otherwise, if the conflict was caused by a material order requirement, then the supply or demand available date plus any applicable offset is reported.	Date	
Id	A unique string identifier for this record. This value is a concatenation of the baselined project name, project site, task Id that had the conflict, and certain details of the constraint or material order link that caused the conflict.	String	Yes
Task	A reference to the task that had a conflict at the point when the project was baselined. **Referenced table:** Task	Reference	
TaskLink	If the conflict in the baselined project was caused by a material order link, this contains a reference to the BaselineTaskLink record having details of the demand or supply order link that caused the conflict in the baselined project. **Referenced table:** BaselineTaskLink	Reference	Yes
Type	Indicates the phase in task scheduling where the conflict was detected in the baseline project. Because project tasks can be scheduled either from the project start date or the project finish date (based on a **ProjectType** setting), conflicts can exist in either direction. Valid values are: • **Primary**—Indicates that the task conflict exists as the project is currently scheduled. For example, if the project has a **ProjectType.ScheduleRule** value of "FromStart", then this value indicates the conflict occurs when scheduling tasks from the project start date. This type of conflict typically requires investigation. • **Secondary**—Indicates a conflict that does not present itself as the project is currently scheduled. For example, if the project has a **ProjectType.ScheduledRule** of "FromStart", then this value indicates the conflict would occur if scheduling tasks from the project finish date. This type of conflict can typically be ignored.	String (Enum)	

Table 6.29: BaselineConflict (ProjMgmt) fields

Field name	Description	Data type	Key
Source	Indicates whether the scheduling conflict in the baselined project was caused by a task constraint or a material order requirement from a demand or supply order. Valid values are: • Constraint • Demand • Supply	String (Enum)	

BaselinePlannedOrder table

The **BaselinePlannedOrder** input table lists planned orders imported from an ERP system. This table supports data validation and is used for internal purposes only.

Table 6.30: BaselinePlannedOrder (Mfg) fields

Field name	Description	Data type	Key
DueDate	Due date of the imported planned order.	Date	
Model	The model that applies to this imported planned order. Ignored in data validation if either **Part.MUEPoolNettingType.ModelRule** is set to "Ignore" or Model-Unit Effectivity is not enabled. **Referenced table:** Model	Reference	
Part	The part the imported planned order is for. **Referenced table:** Part	Reference	
Pool	The pool that applies to this imported planned order. Ignored in data validation if either **Part.MUEPoolNettingType.ModelRule** is set to "Ignore" or Pool is not enabled. **Referenced table:** Pool	Reference	
Quantity	The amount of the imported planned order.	Quantity	
StartDate	The start date for the imported planned order.	Date	
StartUnit	The start unit that applies to this imported planned order. Ignored in data validation if either **Part.MUEPoolNettingType.UnitRule** is set to "Ignore" or Model-Unit Effectivity is not enabled.	Integer	

BaselineTaskLink table

The **BaselineTaskLink** table contains details of any material supply or demand links defined for a project's tasks at the point when the project was baselined (copied to the baseline scenario), along with the associated part link. For each supply or demand link associated with a task in a baselined project, details of that link are reported such as the order id and line number, the quantity assigned to the task, and whether or not the order's availability impacts the task finish date. These details can be used for comparison against the material supply or demand links defined in the current or working version of the project.

Table 6.31: BaselineTaskLink (ProjMgmt) fields

Field name	Description	Data type	Key
ApplyConstraint	Indicates if the available date of the linked demand or supply can potentially constrain the task start or finish date. Valid values as taken from the **ApplyConstraint** field on either the **TaskDemandLink** or **TaskSupplyLink** tables are. • **N** • **Y**	Boolean	
Assigned Quantity	If this record pertains to an order requirement in the baselined project, then this is the amount of the order assigned to this task. That is, the value from the **AssignedQuantity** field on either the **TaskDemandLink** or **TaskSupplyLink** record.	Quantity	
AvailableDate	If this record pertains to an order requirement in the baselined project, then this is the date the order is expected to be available. That is, the value from the **AvailableDate** field on either the **IndependentDemand** or **ScheduledReceipt** record.	Date	
Critical	If this record pertains to an order requirement in the baselined project, then this indicates if the order's availability impacts the task finish date. That is, the value from the **Critical** field on either the **TaskDemandLink** or **TaskSupplyLink** record.	Boolean	
Id	A unique string identifier for this record. When a project is baselined in RapidResponse, this value is a concatenation of the task's Id, project name, along with details of the part, demand, or supply that were linked to the task in the associated task link record.	String	Yes
Line	If this record pertains to an order requirement in the baselined project, then this indicates the specific line item of that order. That is, the value from the **Line** field on either the **IndependentDemand** or **ScheduledReceipt** record.	String	

Table 6.31: BaselineTaskLink (ProjMgmt) fields

Field name	Description	Data type	Key
MaterialCost	The cost of the parts linked to the task at the point when the project was baselined. Based on the corresponding **MaterialCost** field in either the **TaskPartLink**, **TaskDemandLink**, or **TaskSupplyLink** table.	Money	
Offset	If this record pertains to an order requirement in the baselined project, then this represents the number of days to add to orders available date when determining either the task's start date or finish date (based on the setting in the **Rule** field). Taken from the **Offset** field on the associated **TaskDemandLink** or **TaskSupplyLink** record.	Quantity	
OrderId	If this record pertains to an order requirement in the baselined project, then this indicates the specific line item of that order. That is, the value from the **Order.Id** reference on either the **IndependentDemand** or **ScheduledReceipt** record.	String	
OrderSite	If this record pertains to an order requirement in the baselined project, then this indicates the specific line item of that order. That is, the value from the **Order.Site** reference on either the **IndependentDemand** or **ScheduledReceipt** record.	String	
OrderType	If this record pertains to an order requirement in the baselined project, then this indicates the specific line item of that order. That is, the value from the **Order.Type** reference on either the **IndependentDemand** or **ScheduledReceipt** record.	String	
PartName	The name of the part the task had a material requirement for when the project was baselined. That is, the **Part.Name** value referenced through the **TaskPartLink** record.	String	
PartSite	The site associated with the part that the task had a material requirement for when the project was baselined. That is, the **Part.Site.Value** value referenced through the **TaskPartLink** record.	String	
Quantity	The required quantity of the part associated with the original task link this record pertains to (that is, the **TaskPartLink.Quantity** value).	Quantity	

Table 6.31: BaselineTaskLink (ProjMgmt) fields

Field name	Description	Data type	Key
Rule	If this record pertains to an order requirement in the baselined project, then this defines how, if at all, the order's availability constrains the task completion. Taken from the **Rule** field on the associated **TaskDemandLink** or **TaskSupplyLink** record with one of the following valid values: • FinishDate • None • StartDate	String (Enum)	
Task	A reference to a task that had a material supply or demand requirement defined when the project was baselined. The name of the baselined project this task pertains to can also be accessed through this reference. **Referenced table:** Task	Reference	
Type	Indicates the type of baselined material requirement for the task that this record pertains to. Valid values are: • **Demand**—this record pertains to an independent demand requirement for the task (as set through the **TaskDemandLink** table). • **Part**—this record pertains to a part requirement for the task (as set through the **TaskPartLink** table). • **Supply**—this record pertains to a scheduled receipt requirement for the task (as set through the **TaskSupplyLink** table).	String (Enum)	

BestFitProfile table

The **BestFitProfile** table is used to define groups of statistical models for consideration in best fit statistical forecasting.

Named profiles in this table are referenced by records in the **BestFitProfileDetail** table each of which identifies a particular statistical model and contains parameter values that override corresponding values on the **ForecastItemParameters** table. Thus, each profile is made up of the models and associated parameter values that reference it from **BestFitProfileDetail** table. This can include multiple instances of the same model in a given profile. For example, the "MovingAverage" model might be added to the same profile multiple times with each instance specifying a different range over which to collect data for use in calculating that moving average.

The **BestFitProfile** table is also referenced by the **ForecastItemParameters** table. This allows forecast items using the "BestFit" method to evaluate only select models during the best fit process. For example, if a known subset of models are known to be generally applicable for a given forecast item, then a profile consisting of the appropriate models can be defined and referenced by that item. This can save processing time associated with evaluating models that are known to not fit well with the item's data. Otherwise, if the **ForecastItemParameters.BestFitProfile** reference is Null, then all RapidResponse forecast models (other than the optional "Rforecast" model) are considered during the best fit process and the applicable model parameters are taken from the **ForecastItemParameters** record.

Table 6.32: BestFitProfile (Mfg) fields

Field name	Description	Data type	Key
Description	A description of this profile. For example, this might describe the group of models that belong to the profile.	String	
Name	A unique identifier for this profile. This value is referenced from the **ForecastItemParameters** and **BestFitProfileDetail** tables.	String	Yes

BestFitProfile table – calculated and set fields

The following describes the calculated and set fields in the **BestFitProfile** table. For an introduction to this table, and descriptions of its input fields, see "BestFitProfile table" on page 209.

Table 6.33: Calculated BestFitProfile (Mfg) fields

Field name	Description	Data type	Key
BestFitProfile Details	Set of **BestFitProfileDetail** records that belong to this profile.	Set	
ForecastItem Parameters	Set of **ForecastItemParameters** records that use this profile.	Set	

BestFitProfileDetail table

The **BestFitProfileDetail** table holds the detailed records that make up each best fit profile.

Each record in this table specifies a given statistical forecast model, select model parameters that override corresponding values in the **ForecastItemParameters** table, and contains a reference to the **BestFitProfile** table. Together, all records that reference the same **BestFitProfile** record define the subset of statistical models that belong to the profile. Thus, only that subset of models is considered during best fit forecasting for items referencing the profile through **ForecastItemParameters.BestFitProfile**. Otherwise, if **ForecastItemParameters.BestFitProfile** is Null, then all standard RapidResponse forecast models are evaluated if the item uses the "BestFit" method and the corresponding model parameters in the **ForecastItemParameters** table are used instead. For more information, see ForecastItemParameters table.

Note: There may be instances where you want a forecast item to reference a group of statistical models that are defined in **BestFitProfile**, but you do not want to use the model parameter values that are associated with the profile in the **BestFitProfileDetail** table. To do this, you can set **ForecastItemParameters.IgnoreBestFitProfileDetailParameters** to **"True"** to ignore the model parameter values in the **BestFitProfileDetail** table and apply the values from **ForecastItemParameters** instead. See "IgnoreBestFitProfileDetailParameters" on page 302.

Note: Multiple records for a given statistical model can be defined and associated with the same entry in the **BestFitProfile** table. For example, if the "HoltWintersMethod" is used, there might be a requirement to evaluate the model using different seasonal interval counts. Similarly, a given model might be evaluated multiple times using different amounts of historical data in each instance.

Table 6.34: BestFitProfileDetail (Mfg) fields

Field name	Description	Data type	Key
AutoRegressive Terms	Specifies the auto-regression terms used in an ARIMA forecast calculation. Values for this field are typically a list of lag numbers. For example, 1,2,4 specifies that the ARIMA model should consider lags 1, 2, and 4 when calculating the statistical forecast. **Default value**: ' '	String	
BestFitHoldout PeriodInterval Count	Defines the duration of the holdout period used for best fit forecasting (expressed in intervals of the **SOPAnalyticsConfiguration.CycleCalendar**) The holdout period is applied immediately before **RunDate** and is made up of the historical periods whose data is held out (excluded) when fitting statistical models to historical data. Instead, this period is used for evaluation purposes as simulated forecasts based on each of the models fitted to earlier history is compared against the actuals in the holdout region. The model that most accurately predicts the values in the holdout region, based on minimizing the chosen error measure, is then used to generate the forecast starting at **RunDate**. **Default value**: 0 **Note:** This field is only applicable to items with **ForecastItemType.HoldoutPeriodUsageRule** set to "SimpleHoldout" or "Simulation". For more information, see "Using best fit with a holdout period" on page 2053.	Integer	
Constant	Indicates whether a constant value, also known as the Y intercept, is included in an ARIMA or ARIMAX forecast calculation. Valid values are: • **Use**— The constant is used in the calculation. • **Ignore**—For ARIMA, The constant is not used in the calculation. For ARIMAX, **Ignore** forces the constant term to be zero. **Default value**: Ignore	String (Enum)	

Table 6.34: BestFitProfileDetail (Mfg) fields

Field name	Description	Data type	Key
DifferenceLevel	The number of differencing operations to perform when calculating an ARIMA or ARIMAX function. If you enter a negative DifferenceLevel using ARIMA, ARIMA is not used. However, if you enter a negative DifferenceLevel using ARIMAX, the order is automatically chosen. **Default value**: -1 **Note:** It is strongly recommended that you do not enter a value that is greater than 2 in this field.	Integer	
ElasticNetParameter	A parameter, also known as alpha, that can be from 0 to 1 (inclusive) that controls how much penalization of the L1 and L2 norms is applied when using the Elastic Net forecast model. Elastic Net combines both the LASSO and ridge regression techniques to shrink coefficients. The value 1 is equivalent to LASSO and 0 is equivalent to ridge. This parameter works in conjunction with **RegularizationParameter**. **Default value**: 1 **Note:** This field was added in Version 2016.2, Service Update 27.	Quantity	

Table 6.34: BestFitProfileDetail (Mfg) fields

Field name	Description	Data type	Key
ForecastModel	Indicates the statistical model that will be fitted to the historical data and then evaluated for best fit. Based on the model selected, parameter values might need to be specified in certain other fields. Valid values are: • **AdditiveHoltWintersMethod**—similar to HoltWintersMethod, but forecast points are calculated in an additive rather than multiplicative, manner. Suitable for demand that has constant variation over a period. For more information, see "Holt-Winters multiplicative and additive" on page 2037. • **ARIMA**—calculates forecasts for a time period using a linear combination of actual values and error values in a time series. This model can be used on a stationary time series, or a differencing function can be applied to non-stationary data to make it stationary. For more information, see "Auto-Regressive Integrated Moving Average (ARIMA)" on page 2034. • **ARIMAX**—Is an extension of the ARIMA model, but also includes independent variables (regressors) in the forecast calculation. This makes ARIMAX a multiple linear regression model. To improve forecast accuracy, ARIMAX also takes into consideration autocorrelation that may be found in regressor residuals. For a more detailed description, see "ARIMAX" on page 2042. • **BestFit—**fits each of the other forecast models and selects the one with the least margin of error. Although this is an available option in the **BestFitProfileDetail** table, it should not be selected when defining best fit profiles. If this option is selected on a **BestFitProfileDetail** record, the record will be ignored within the profile. For a more detailed description, see "Best fit" on page 2053. • **CrostonsMethod**— uses exponential smoothing with a single smoothing constant for the forecast values, but calculates two different values; the first being the forecast values at a point and the second being the average length of time between forecasts. These values determine the forecast quantities and the periods that have forecast demands. Suitable for demand that is not constant, such as lumpy demand that contains periods of zero quantities. For more information, see "Croston's method" on page 2034. • **DoubleExponentialSmoothing**—considers the data points and trends within the historical data, and applies a smoothing algorithm to both. The result is then used as the statistical forecast. Suitable for demand that is fairly stable but trending up or down over time. For more information, see "Double	String (Enum)	

Table 6.34: BestFitProfileDetail (Mfg) fields

Field name	Description	Data type	Key
	exponential smoothing" on page 2036. • **ElasticNet**—A multiple linear regression model that uses regularized, also known as penalized, regression methods. It blends Lasso and ridge regression techniques by penalizing both L1 and L2 norms to reduce the coefficient vector. To use ElasticNet, you must attach a minimum of two regressors to a forecast item or you won't be able to generate a statistical forecast. For a more detailed description, see "ElasticNet" on page 2043. • **ExponentialSmoothing**— considers data points within the historical data, and applies a smoothing algorithm. The result of the final data point is then used as a constant value for the statistical forecast. Suitable for demand that is fairly stable and lacks a trend. For more information, see "Exponential smoothing" on page 2037. • **HoltWintersMethod**—similar to double exponential smoothing in that it considers data points and trends within the historical data, but also accounts for seasonal trends. That is, the values for each point in the forecast and trend are further adjusted to account for seasonal demand changes. This model is the Holt-Winters multiplicative method, so it is suitable for demand that has proportional variation over a period. For more information, see "Holt-Winters multiplicative and additive" on page 2037. • **Linear**—performs a linear regression on a set of historical data points to generate a trend line that determines statistical forecast quantities. Suitable for demand that does not fluctuate. For more information, see "Linear" on page 2039. • **MovingAverage**—calculates the simple moving average of a specified number of previous data points to generate a constant forecast. Suitable for demand that is fairly stable and does not change much over time. For more information, see "Moving average" on page 2039. • **MultipleLinearRegression**—Performs a linear regression using multiple independent variables to predict the outcome of one dependent variable. For a more detailed description, see "Multiple linear regression" on page 2043. • **Rforecast**—uses a statistical model as defined in the R statistical programming language. If selected, the RParameterSet reference can be used to identify parameters associated with the intended model. This option supports the optional R Forecast capability. For more information, see "Rforecast" on page 2039. Note		

Table 6.34: BestFitProfileDetail (Mfg) fields

Field name	Description	Data type	Key
	also that "Rforecast" is only considered in the best fit process for item's that use a BestFitProfile. That is, if an item's BestFitProfile reference is Null, then all models other than "Rforecast" will be considered during best fit forecasting). • **StepWiseARIMA**—identical to the ARIMA model, but all parameters are calculated automatically. Step-wise ARIMA selects the order of difference through KPSS unit-root tests and selects AR order and MA order by minimizing AIC. For more information, see "Step-wise ARIMA" on page 2039.		
Historical IntervalCount	The number of periods of historical demand to use as input into generating the statistical forecast. Expressed in units of the **IntervalsCalendar** on the **ForecastItemParametersType** table (the value applicable to the given forecast item).	Integer	
Id	A unique string identifier for this record.	String	Yes
MovingAverage IntervalCount	Specifies the number of periods of historical demand to use in calculating statistical forecasts using the "MovingAverage" model. Expressed in units of the **IntervalsCalendar** on the **ForecastItemParametersType** table (the value applicable to the given forecast item). **Note:** If this value is less than or equal to zero (0), then this value is automatically calculated so to minimize the selected error measure.	Integer	
Moving AverageTerms	Specifies the number of moving average terms used with the ARIMA method. Values for this field are typically a list of lag numbers. For example, 2,3 specifies the ARIMA model considers lags 2 and 3 when calculating the statistical forecast. Default value: ' '	String	
Profile	A reference to the best fit profile the statistical forecast model and other parameters on this record belong to. **Referenced table:** BestFitProfile	Reference	Yes

Table 6.34: BestFitProfileDetail (Mfg) fields

Field name	Description	Data type	Key
RegularizationParameter	A parameter, also known as lambda, that controls the strength of the penalty term for coefficients that is used in Elastic Net regression. This parameter is dependent on the ElasticNetParameter to shrink the coefficients of regressors. If you set a negative value in this field, RapidResponse will choose a value for you. **Default value**: -1 **Note:** This field was added in Version 2016.2, Service Update 27.		
RParameterSet	A reference to a grouped set of parameters used to define the function being used from the R programming language. This field is typically populated when the ForecastModel is set to "Rforecast" and is only available if the optional R Forecast capability has been configured. **Referenced table:** RParameterSet (Nullable)	Reference	
Seasonal IntervalCount	Specifies the duration of a season for forecasts calculated using the "BestFit", "Elastic Net", "HoltWintersMethod", "MultipleLinearRegression", or "Rforecast" models. Expressed in units of the **IntervalsCalendar** on the **ForecastItemParametersType** table (the value applicable to the given forecast item). **Default value**: -1	Integer	
TrendDecay Factor	A decay factor that can be applied to the following forecast models: • AdditiveHoltWintersMethod • DoubleExponentialSmoothing • ElasticNet • HoltWintersMethod • MultipleLinearRegression For AdditiveHoltWintersMethod, DoubleExponentialSmoothing, and HoltWintersMethod, if the trend should decay over time, this value must fall between 0 and 1. All values less than 0 result in complete elimination of the trend. If neither decay nor elimination is required, this value should be 1 or greater. For ElasticNet and MultipleLinearRegression, a value that is equal or less than 0 will result in complete elimination of the trend. If neither decay nor elimination is required, this value should be 1 or greater. The use of the decay factor is controlled by the **TrendDecayFactorRule** option on the **ForecastItemParametersType** table.	Quantity	

BestFitProfileDetail table – calculated and set fields

The following describes the calculated and set fields in the **BestFitProfileDetail** table. For an introduction to this table, and descriptions of its input fields, see "BestFitProfileDetail table" on page 210.

Table 6.35: Calculated BestFitProfileDetail (Mfg) fields

Field name	Description	Data type	Key
ForecastItem Parameters	Set of **ForecastItemParameters** records that reference this record, and thereby lock the best fit method to always select the specified model (and applicable parameters) for the item. **Referenced table:** ForecastItemParameters	Set	
ForecastItem ParametersFit Outputs	Set of **ForecastItemParametersFitOutput** records that reference this record. **Referenced table:** ForecastItemParameterFitOutput	Set	

BillOfMaterial table

The **BillOfMaterial** table identifies parent and child relationships between assembly parts (products assemblies and sub-assemblies) and component parts (assemblies, sub-assemblies, and raw materials) used in the production of the assembly.

RapidResponse can explode bill of material records with a negative QuantityPer value. Negative QuantityPer values are ignored unless the bill record has a **Type.ExplodeNegatives** control value of **Y**, or a **Type.ProductType** control value of either "CoProduct" or "ByProduct". For information about negative dependent demands, see "Exploding bill records with a negative QuantityPer value" on page 1338.

Table 6.36: BillOfMaterial (Mfg) fields

Field name	Description	Data type	Key
Alternate	A reference to the alternate BOM to which this component belongs. When Netting logic performs explosion calculations for dependent demands, this value is matched to either **PartSource.BOMAlternate** or **ScheduledReceipt.BOMAlternate**. If this value matches the default record in the **BOMAlternate** table, then the component is used by all 'Make' part sources and scheduled receipts for this assembly. For more information about alternate BOMs, see "Alternate BOM calculations" on page 1759. For information about identifying the "default" **BOMALternate** record, see "Default BOMAlternate record" on page 1764. **Referenced table**: BOMAlternate	Reference	
Assembly	The assembly being produced. **Referenced table:** Part **Reference Syntax:** Assembly.Site, Assembly.Name **Note:** If you have upgraded to Version 2015.3 and enabled record uniqueness on this table prior to the upgrade, this field is a key field. For more information, see "Key fields" on page 141.	Reference	
BaseKey	Can optionally be used to uniquely identify each BillOfMaterial record. **Note:** If you have upgraded to Version 2015.3 and enabled record uniqueness on this table prior to the upgrade, this field is a key field. For more information, see "Key fields" on page 141.	String	
Component	The component used to produce the assembly. **Referenced table:** Part **Reference Syntax:** Component.Site, Component.Name **Note:** If you have upgraded to Version 2015.3 and enabled record uniqueness on this table prior to the upgrade, this field is a key field. For more information, see "Key fields" on page 141.	Reference	
EffectiveInDate	Date on which this BillOfMaterial record will be effective. For more information, see "BOMType table" on page 687. **Default value**: Past	Date	
EffectiveInEC	The engineering change that introduced this BillOfMaterial record. **Referenced table:** EngineeringChange (this reference is nullable in new installations of RapidResponse 10.1 and later). **Reference Syntax:** EffectiveInEC.Id	Reference	

Table 6.36: BillOfMaterial (Mfg) fields

Field name	Description	Data type	Key
EffectiveOutDate	Date on which this BillOfMaterial record is no longer in effect. **Default value**: Undefined	Date	
EffectiveOutEC	The engineering change that makes this BillOfMaterial record obsolete. **Referenced table:** EngineeringChange (this reference is nullable in new installations of RapidResponse 10.1 and later). **Reference Syntax:** EffectiveOutEC.Id	Reference	
EndUnit	The end of the unit range to which this BillOfMaterial record applies. The end unit is either included in the range or excluded depending upon the values of the BOMType.EffectivityRule and DependentUnitRule. This field is ignored unless BOMType.MUERule is 'Unit' or 'ModelUnit'. Every supply will be seen as being before EndUnit if less than zero. **Default value**: -1 **Note:** This field supports the Model-Unit Effectivity analytic and is ignored if this capability is not enabled.	Integer	

Table 6.36: BillOfMaterial (Mfg) fields

Field name	Description	Data type	Key
FeatureRule	If this record pertains to a configurable end-item (that is, a made to order assembly where **PartType.FeatureBOMRule** is other than "Ignore"), then this field is used to specify a feature-based rule defining the conditions under which the component is needed in supplies satisfying assembly demands. For example, a component might only be required in production of the assembly if a given demand contains a particular set of features. To determine if the component is required to satisfy a given assembly demand, the specified rule is evaluated against the string of features provided in **IndependentDemand.FeatureList**. This rule can be comprised of feature names as well as any of the following logical operators. • **And**—used to indicate multiple features that must all be present on the assembly demand for the component to be used in satisfying it. By default, an ampersand character (&) is used to represent "and". For example, *a1 & b2*. If necessary, a different "and" symbol can be chosen by an administrator as discussed in "Defining the And operator for feature rules" on page 2208. • **Or**—used to indicate multiple features any one (or more) of which must be present on the assembly demand for the component to be used in satisfying it. A comma (,) is used to represent "or" and the specified features should also be enclosed in parentheses. For example, *(a1, a2, a3)*. • **Not**—used to indicate features that must not be present on the assembly demand for the component to be used in satisfying it. An exclamation (!) is used to represent "not". For example, *! (a1, a3) & b2*. If this field is left blank, then the component is assumed to be required in supplies satisfying any demand for the assembly regardless of features. **Default value**: blank string	String	

Table 6.36: BillOfMaterial (Mfg) fields

Field name	Description	Data type	Key
IntervalToExpiry Offset	If the BillOfMaterial record represents a co-product or by-product configuration, this field indicates the number of intervals to add to or subtract from the assembly's **PartSource.IntervalsToExpiry** and **PartSource.CTPIntervalsToExpiry** values when calculating estimated and actual expiry dates on the co-product or by-product. These intervals are expressed in terms of the assembly part's **PlanningCalendars.ExpiryCalendar** value. This setting allows for a co-product or by-product to have a different shelf life than the primary part whose production it is derived from. If the co-product or by-product has a longer shelf life than the primary part, this field should be set to a positive value. If the co-product or by-product has a shorter shelf life than the primary part, this field should be set to a negative value. Otherwise, this value should be left at zero. **Default value**: 0	Integer	
LeadTimeOffset	Specifies the number of units defined by the **Assembly.PlanningCalendars.TimeUnits** calendar (typically, workday) to offset (move later) the required **DueDate** of the components for use in the assembly. Allows material to be staggered in time for long assembly operations. If the BillOfMaterial record defines a co-product or by-product configuration, this field allows for the due and available dates on the co-product or by-product to be either earlier or later then the due and available dates on the primary product by a specified amount of time. **Default value**: 0	Quantity	
Model	The model to which this bill record applies. The Model value is ignored unless the MUERule for the BOMType associated with this record is Model or ModelUnit. **Referenced table:** Model **Note:** This field supports the Model-Unit Effectivity analytic, and is ignored if this capability is not enabled.	Reference	

Table 6.36: BillOfMaterial (Mfg) fields

Field name	Description	Data type	Key
Operation	The specific operation in the assembly supply's routing where the component is used. The referenced operation can be in the routing's standard sequence or one of its optional parallel sequences. Use of this field allows dependent demands to be placed at the start of the operation where they are actually needed (which may be after the parent order start date). Note that this reference is only considered if the parent supply uses capacity-based variable lead time (**OrderPolicy.UseVarLeadTime** set to "CRP"). **Referenced table:** CRPOperation (nullable) **Reference Syntax**: Operation.Id, Operation.Sequence.Id, Operation.Sequence.Routing.Id, Operation.Sequence.Routing.Site.	Reference	
OperationNumber	Operation sequence number at which the component is needed. This value is not used in Netting calculations, and refers to operations defined in the **Operation** table only. **Default value**: 0	Integer	
OptionRatio	Probability the assemblies will need these components. The range should be between 0 - 1 (if **BOMType.RatioRule** = 'Fraction') or between 1 - 100 (**BOMType.RatioRule** = 'Percent'). The supply quantity is multiplied by the ratio, then rounded (depending on rounding rules), then multiplied by QuantityPer (and possibly rounded again according to the rounding rules). MRP bills have this set to '1' or '100'. **Default value**: 1 **Note:** This field is ignored on BillOfMaterial records that define co-product or by-product configurations.	Quantity	
QuantityPer	The amount of this component that is required to build each finished assembly. A negative value can be processed to cancel positive demand. If the BillOfMaterial record defines a co-product or by-product configuration, then a negative quantity per should be used to define the amount of the supply generated for the primary product that ends up as a co-product or by-product. This is done using the ratio `-(co or by-product% / primary product%)` For more information about configuring co-products and by-products, see "Co-products and by-products" on page 1581. **Default value**: 1	Quantity	

Table 6.36: BillOfMaterial (Mfg) fields

Field name	Description	Data type	Key
Scrap	Specifies the fraction of the components that is lost during the production of the assembly. For example, due to breakage. The interpretation of the value specified in this field is configurable as described in "ScrapRule" on page 694. **Default value**: 1 **Note:** This field is ignored on BillOfMaterial records that define co-product or by-product configurations.	Quantity	
Shop	The shop floor location associated with this BillOfMaterial record. **Referenced table**: Shop (this reference is nullable in new installations of RapidResponse 10.1 and later).	Reference	
StartUnit	The beginning of the unit range to which this bill record applies. The start unit is either included in the range or excluded depending upon the values of the BOMType EffectivityRule and DependentUnitRule. StartUnit is ignored unless MUERule is Unit or ModelUnit. Every supply will be seen as being after StartUnit if StartUnit is less than zero. **Default value**: -1 **Note:** This field supports the Model-Unit Effectivity analytic, and is ignored if this capability is not enabled.	Integer	
SubstituteGroup	A reference to the **SubstituteGroup** table that is used to define groups of substitutable components within an assembly. All components that are assumed to be substitutable for one another within a given assembly must point to the same **SubstituteGroup** record. In cases where an entire group of components can be substituted for another group of components, the **SubstituteGroup** reference should be made on the phantom BOM that defines each group of components. To ensure expected results/performance in bom-level substitution, avoid having multiple assemblies reference the same group for their substitutable components. That is, each assembly should have its own unique **SubstituteGroup** record(s) available for grouping substitutable components. **Referenced table:** SubstituteGroup (this reference is nullable in new installations of RapidResponse 10.1 and later). **Note:** This field is ignored on BillOfMaterial records that define co-product or by-product configurations. However, co-products can still be defined as substitutable components under an assembly (that is, each co-product should be configured as a component with the primary part in the group as the assembly).	Reference	

Table 6.36: BillOfMaterial (Mfg) fields

Field name	Description	Data type	Key
SubstitutionTo DateQty	Indicates the quantity to date that has already been allocated to this substitute BOM (for example, it might represent known allotments on input supplies). This value should be expressed in component stock units, and is then used as an initial value for ongoing BOM-level substitution decisions. This field is applicable to substitute BOM records where **SubstituteGroup.Type.SourceRule** is set to "OnGoing", and is used in the logic that determines which substitutable components in a group should have planned orders generated on them to satisfy a dependent demand from the assembly. For more information, see "Define planned order generation" on page 1571.	Quantity	
Substitution Sequence	Defines the preferred sequence in which an assembly should look for scheduled/input supply within a group of substitutable components (components with lower values are used first). A value of 0 should be assigned to the primary component in the group. When substitution logic is turned off for the group (or if there is no **SubstituteGroup** record defined), the primary component is the only one for which dependent demand is generated when supply for the assembly is exploded. Also, ensure that no two of an assembly's components in a given **SubstituteGroup** have the same value in this field (duplicate **SubstitutionSequence** values in a group can result in excess dependent demand being generated). For more information, see "Substitute BOM configuration" on page 1566. In cases where an entire group of components can be substituted for another group of components, the component with the lowest value in this field acts as the indicator component within the group (the component whose supply determines if substitutions can be made). For example, a value of -1 could be assigned to the indicator component, and all other components in the group could be given higher values. If all values are the same, RapidResponse will use the component with the highest **Part.StdUnitCost** as the indicator. For more information, see "Substituting groups of components" on page 1574 **Default value**: 0 **NOTE**: This value defines a preference between substitutable components only when they can provide scheduled supply equally well (on-time or least late). For example, if Component A has scheduled supply that is on-time to the demand and Component B has scheduled supply that is late to the demand, then the supply of A is preferred regardless of the value in this field.	Integer	

Table 6.36: BillOfMaterial (Mfg) fields

Field name	Description	Data type	Key
Target	Determines the ratio, or percentage, in which dependent demand from the assembly is exploded down to the components in a substitute group when creating planned orders. This value should be expressed in terms of the assembly's supply unit. The percentage of demand that should be exploded down to a given component is then calculated as the **Target** value for the component divided by the sum of the **Target** values across all components in the group. Note that depending on the setting in the **ComponentSourceRule** field on the **SubstituteGroupType** table, each dependent requirement from the assembly is either split proportionally between substitutable components or fully assigned to the substitutable component which would otherwise be furthest away from its ongoing target. If planned orders should only be created on the primary component in the group, then it can be assigned a positive value in this field and all other components should be assigned a value of 0 (zero). If planned orders should be evenly spread across all components in the group, then each can be assigned the same postive value in this field (for example, a value of 1 could be specified). **Default value:** 0 **Note:** This value defines a preference between substitutable components only when they can plan new supply supply equally well (on-time or least late). For example, if Component A can plan a new order that is one day late to the demand and Component B can plan a new order that is five days late to the demand, then the entire dependent demand is placed on A regardless of the value in this field.	Quantity	
Type	A value that is associated with processing rules that defines the explosion, effectivity, and netting behavior. This field references the BOMType table. **Referenced table:** BOMType	Reference	

BillOfMaterial table – calculated and set fields

The following describes the calculated and set fields in the BillOfMaterial table. For an introduction to this table, and descriptions of its input fields, see "BillOfMaterial table" on page 217.

Table 6.37: Calculated BillOfMaterial (Mfg) fields

Field name	Description	Data type	Key
AssemblyLLC	The low-level code of the assembly. This field is intended for internal use in propagating the LLC down from the assembly to the component.	Integer	
CumLeadTime	The component's CumLeadTime adjusted by the **LeadTimeOffset**. Cumulative lead time is calculated using BillOfMaterial records that are effective at the MRP date. If a component is treated as a phantom to a bill, the component's lead-time is subtracted from its cumulative lead time. For example, only its component cumulative lead times are used. If it is not a phantom, or conditionally a phantom, then it is assumed to contribute its lead-time. Parts that are Buy parts will have cumulative lead time equal to its lead-time, (for example, it will not consider the lead-times of the components). This calculation is done only within a part's site. For multi-site cumulative lead time calculations (that is, calculations that consider transfer part sources), use the **MultiSiteCumLeadTime** field. For more information about lead time, see "Lead time calculations" on page 1307. **NOTE**: If using time-phased lead time. then the lead times effective for the component's primary part source at the latter of the part's **RunDate** or **PartSource.FirstEffectiveDate** are used in this calculation.	Quantity	
EffOffSet	This value reflects the value of the LeadTimeOffset field but will be zero if the UseLeadTimeOffset field is 'N'. This value is based on the value of: BillOfMaterial.Type.UseLeadTimeOffset (if UseLeadTimeOffset= 'N' then EffOffset=0, otherwise EffOffset= LeadTimeOffset.)	Quantity	
EffOptionRatio	This field reflects the value of the OptionRatio field expressed as a fraction (value between 0 and 1). However, it always returns 1 if Type.RatioRule is set to 'Ignore'.	Quantity	

Table 6.37: Calculated BillOfMaterial (Mfg) fields

Field name	Description	Data type	Key
EffQuantityPer	The effective quantity of the component per unit of the assembly (after consideration for **Scrap** value and the setting in **BOMType.ScrapRule**). If **BOMType.RoundingRule** is set to "QtyPerOrder", then this field is always set to the **QuantityPer** value (all other **RoundingRule** settings are ignored by this field). If **BOMType.RoundingRule** is not set to "QtyPerOrder", then this calculation is dependent on ScrapRule as follows: 1. ScrapFraction BillOfMaterial.QtyPer / (1 - BillOfMaterial.Scrap) 2. ScrapPercent BillOfMaterial.QtyPer / (1 - BillMaterial.Scrap * 0.01) 3. YieldFraction BillOfMaterial.QtyPer / BillMaterial.Scrap 4. YieldPercent BillOfMaterial.QtyPer / (BillMaterial.Scrap * 0.01) 5. InflationFraction BillOfMaterial.QtyPer / (1 / (1 + BillOfMaterial.Scrap)) 6. InflationPercent BillOfMaterial.QtyPer / (1 / (1 + BillOfMaterial.Scrap * 0.01))	Quantity	
FirstEffectiveDate	Represents the adjusted value for the EffectiveInDate taking into account Type.EffectivityRule (for example, 'Inclusive'). If the record will never be effective, the dates will be 'Undefined'.	Date	
FirstEffectiveUnit	The first unit to which this BillOfMaterial record applies. **Note:** If not using Unit Effectivity, this field is set to –1.	Integer	
IsRecursive	Indicates whether recursive data has been found during processing (this happens when a part ends up being a component of itself). BillOfMaterial records that have a BOMType.EffectivityRule of 'Never' are ignored. Valid values are: • **Y**—recursive data has been found. The calculation skips the parts involved in the recursive relationship. • **N**—recursive data has not been found	Boolean	
LastEffectiveDate	Represents the adjusted value for the EffectiveOutDate taking into account Type.EffectivityRule (for example, InclusiveExclusive). This field is always inclusive. If the record will never be effective, the dates will be 'Undefined'.	Date	

Table 6.37: Calculated BillOfMaterial (Mfg) fields

Field name	Description	Data type	Key
LastEffectiveUnit	The last unit to which this BillOfMaterial record applies. **Note:** If not using Unit Effectivity, this field is set to 2,147,483,647.	Integer	
MultiSite AssemblyLLC	The multi-site low level of the assembly (any "transfer" part sources and their bill of material structures are considered in this calculation). This field is intended for internal use in propagating the low level code down from the assembly to the component.	Quantity	
MultiSiteCum LeadTime	The component's cumulative lead time, calculated using BillOfMaterial records that are effective at the MRP date, adjusted by **LeadTimeOffset**. This field uses a calculation similar to the **CumLeadTime** field, however this calculation will follow a component's product structure across site boundaries. That is, if a component's product structure contains a part with a primary supply type of "transfer", then cumulative lead time associated with the transfer part is included in the value reported in this field. Because this field adds together different lead time values without specifying the calendar to be used in the calculation, it is possible that the different lead time values reported when a product structure crosses site boundaries may not all use the same calendar. Therefore, depending on the calendars used in different sites, this field may not always return the expected result. For more information about lead time, see "Lead time calculations" on page 1307. **NOTE**: If using time-phased lead time. then the lead times effective for the component's primary part source at the latter of the part's **RunDate** or **PartSource.FirstEffectiveDate** are used in this calculation.	Quantity	
FeatureRulesList	Set of BillOfMaterialFeatureRule records that reference this BillOfMaterial record.	Set	
NewAllocations	Set of NewAllocation records that define the dependent demands on the component due to ScheduledReceipts of the assembly that were exploded in RapidResponse.	Set	
Planned Allocations	Set of PlannedAllocation records that define the dependent demands on the component due to PlannedOrders generated for the assembly in RapidResponse.	Set	

Visualizing the bill of material in a BOM chart

Some workbooks can include a chart that shows the bill of material. A BOM chart provides you with an up-to-date view of the product structure, and you can filter the chart to focus only on the components

or sites (or other criteria) that are relevant to you. The BOM Visualization worksheet in the BOM Analysis workbook includes a BOM chart.

In a BOM chart you can:

- Control your view by moving the whole chart, moving individual nodes, or zooming in and out of the chart.
- Focus on a single component and its relationships.
- View substitutes, co-products, and by-products for all components or a specific component.
- Reset the chart to return to its default view.

For more information, see the *RapidResponse User Guide*.

BOMAlternate table

For RapidResponse configurations using alternate BOM logic, this table holds all alternate BOMs (that is, named variations of an assembly's BOM).

One record in this table is the "default" record and contains a special or common alternate code to be used by components that belong to all alternate BOM configurations under a given assembly. Typically, this special **BOMAlternate** record will have an empty string (<blank>) in the **Value** field. For information about finding the default **BOMAlternate** record, see "Default BOMAlternate record" on page 1764.

Table 6.38: BOMAlternate (Mfg) fields

Field name	Description	Data type	Key
Description	A description of this alternate BOM.	String	
Value	The name of this alternate. Each alternate BOM value can be used by many part sources for many different parts. **Default value**: blank	String	Yes

BOMAlternate table – calculated and set fields

The following describes the calculated and set fields in the **BOMAlternate** table. For an introduction to this table, and descriptions of its input fields, see "BOMAlternate table" on page 229.

Table 6.39: Calulcated BOMAlternate (Mfg) fields

Field name	Description	Data type	Key
BillOfMaterials	Set of records in the **BillOfMaterial** table that use this alternate BOM value.	Set	
PartSources	Set of records in the **PartSource** table that use this alternate BOM value.	Set	

Table 6.39: Calulcated BOMAlternate (Mfg) fields

Field name	Description	Data type	Key
Scheduled Receipts	Set of records in the **ScheduledReceipt** table that use this alternate BOM value.	Set	

BonusSchedule table

The **BonusSchedule** table contains string values identifying the different bonus schedules that can be used in RapidResponse. The **Project** and **Task** tables each reference this table to specify the bonus schedule, if any, associated with a given project or task. Bonus schedules are used to determine the bonus revenue applied to tasks or projects that finish in advance of specified bonus dates. That is, bonuses can be earned by projects where **Project.CalcFinishDate** is on or before **Project.BonusDate**, and by tasks where **Task.CalcFinishDate** is on or before **Task.BonusDate**.

Each record in this table is also associated with a set of referencing records in the **BonusScheduleByDate** and/or **BonusScheduleByInterval** tables. These tables define the actual one-time and/or recurring costs that are associated with a given bonus schedule.

This table's records can be edited using the **Bonus Schedules** worksheet in the **Project Master Data** workbook included with RapidResponse. For more information about using this table, see "Bonuses" on page 2196.

Table 6.40: BonusSchedule (ProjMgmt) fields

Field name	Description	Data type	Key
Description	A description of this bonus schedule.	String	
Name	A unique name for this bonus schedule. The value in this field can be referenced from the **Project.BonusSchedule** and **Task.BonusSchedule** fields to set the bonus schedule associated with a given project or task	String	Yes
Site	The site associated with this bonus schedule. **Referenced table**: Site	Reference	Yes

BonusSchedule table – calculated and set fields

The following describes the calculated and set fields in the **BonusSchedule** table. For an introduction to this table, and descriptions of its input fields, see "BonusSchedule table" on page 230.

Table 6.41: BonusSchedule (Mfg) calculated fields

Field name	Description	Data type	Key
BonusByDate	Set of date-based bonus values associated with this bonus schedule.	Set	
BonusByInterval	Set of interval-based bonus values associated with this bonus schedule.	Set	
Projects	Set of projects that use this bonus schedule.	Set	
Tasks	Set of tasks that use this penalty schedule.	Set	

BonusScheduleByDate table

The **BonusScheduleByDate** table holds date effective records used to define the one-time and recurring bonus revenue applicable to a specified bonus schedule. The bonuses on the schedule can then be applied to projects that have a **ProjectType.BonusRule** value of "Date" and/or tasks that have a **TaskType.BonusRule** value of "Date.

For example, this table can be used to set up a bonus schedule that applies a one-time bonus if a project completes before a given date, and also applies a weekly bonus for each week in advance of a given date that the project finishes where the amount of that weekly bonus varies by date.

This table's records can be edited using the **Bonuses by Effective Date** worksheet in the **Project Master Data** workbook included with RapidResponse. For more information about how this table is used, see "Date-based bonus schedules" on page 2197.

Table 6.42: BonusScheduleByDate (ProjMgmt) fields

Field name	Description	Data type	Key
EffectiveOutDate	Sets the last date on which bonuses defined on this record are effective. Bonuses are effective between this date and the **EffectiveOutDate** on the immediately preceding record (by date). If there are multiple effective records between a project or task's finish date and bonus date, then their effective bonus values are used as defined by the setting in the **AccumulationRule** field on either the **ProjectType** or **TaskType** table.	Date	
Id	A unique string identifier for this record.	String	Yes
OneTimeBonus	A one-time bonus to be received if a project or task's **CalcFinishDate** is earlier than its **BonusDate**, and the **EffectiveOutDate** on this record is between **CalcFinishDate** and **BonusDate** (inclusive).	Money	

Table 6.42: BonusScheduleByDate (ProjMgmt) fields

Field name	Description	Data type	Key
PerIntervalBonus	A recurring bonus to be received for each bonus calendar interval between a project or task's **CalcFinishDate** and **BonusDate**. Bonus calendars are defined on the project type or task type; for example, bonuses might be earned on a daily or weekly basis.	Money	
Schedule	A reference to the named bonus schedule the bonus values on this record apply to. **Referenced table**: BonusSchedule	Reference	Yes

BonusScheduleByInterval table

The **BonusScheduleByInterval** table holds interval-based records, expressed in terms of bonus calendar interval, used to define the one-time and recurring bonus revenue applicable to a specified bonus schedule. The bonuses on the schedule can then be applied to projects that have a **ProjectType.BonusRule** value of "Interval" and/or tasks that have a **TaskType.BonusRule** value of "Interval".

For example, assuming a weekly bonus calendar, this table can be used to set up a bonus schedule that applies one set of weekly bonuses if a project finishes up to two weeks earlier than its bonus date, and then applies another set of weekly bonuses if a project finishes more than two weeks before its bonus date.

This table's records can be edited using the **Bonuses by Interval** worksheet in the **Project Master Data** workbook included with RapidResponse. For more information about how this table is used, see "Interval-based bonus schedules" on page 2199.

Table 6.43: BonusScheduleByInterval (ProjMgmt) fields

Field name	Description	Data type	Key
Id	A unique string identifier for this record.	String	Yes
Interval	A number of bonus calendar intervals to subtract from a project or task's **BonusDate** to determine the last effective date for the bonus values defined on this record. Bonuses are effective between this date and last effective date on the immediately preceding record (by interval). If intervals define multiple effective records between a project or task's finish date and bonus date, then their effective bonus values are used as defined by the setting in the **AccumulationRule** field on either the **ProjectType** or **TaskType** table.	Integer	

Table 6.43: BonusScheduleByInterval (ProjMgmt) fields

Field name	Description	Data type	Key
OneTimeBonus	A one-time bonus to be earned if a project or task's **CalcFinishDate** is earlier than its **BonusDate**	Money	
PerIntervalBonus	A recurring bonus to be received for each bonus calendar interval between a project or task's **CalcFinishDate** and **BonusDate**. Bonus calendars are defined on the project type or task type; for example, bonuses might be earned on a daily or weekly basis.	Money	
Schedule	A reference to the named bonus schedule the bonus values on this record apply to. **Referenced table**: BonusSchedule	Reference	Yes

BuyerCode table

The **BuyerCode** table contains a list of buyer codes. This table and the BuyerCode field in the **Part** table have no algorithmic use.

This table's **Site** field is optional, and a system or data administrator can choose whether it uniquely identifies records in the table, or is ignored in queries, and not shown in insert definitions, dialog boxes, or the Data Sources and Mapping window.

Table 6.44: BuyerCode (Mfg) fields

Field name	Description	Data type	Key
Description	A description of this buyer code.	String	
Site	The site associated with this buyer code. This field is optional. **Referenced table:** Core::Site	Reference	Yes
UserId	The user responsible for this buyer code. This field is in the **Solutions** namespace.	String	
Value	A unique identifier associated with this buyer code.	String	Yes

For more information about making the **Site** field optional, see "Modifying table and field properties" in the *RapidResponse Data Integration Guide*.

BuyerCode table – calculated and set fields

The following describes the calculated and set fields in the **BuyerCode** table. For an introduction to this table, and descriptions of its input fields, see "BuyerCode table" on page 233.

Table 6.45: BuyerCode (Mfg) calculated fields

Field name	Description	Data type	Key
Parts	Set of parts associated with this buyer.	Set	

Capacity table

The **Capacity** table identifies the available capacity for a work center at a particular point in time used to schedule the duration of an operation.

Table 6.46: Capacity (Mfg) fields

Field name	Description	Data type	Key
Demonstrated LaborCapacity	The average number of standard labor hours that are actually achieved in a day for the work center. **Default value**: 0	Quantity	
Demonstrated MachineCapacity	The average number of standard labor hours that are actually achieved in a day for the work center. **Default value**: 0	Quantity	
EffectiveInDate	Date this record becomes effective. **Default value**: Undefined	Date	
Efficiency	The factor used to scale operation setup and run times for this work center. In other words, a measurement of what you can hypothetically produce versus what you really are producing. When multiplied with the Utilization factor, the resulting value is the usage factor. This is used for converting the run time and setup time from "standard hours" to real elapsed hours. **Default value**: 1	Quantity	
HoursPerDay	Total number of working hours in a day at this work center. **Default value**: 8	Quantity	
LaborRunRatio	The number of hours of labor required for one standard hour of run time. This factor is used to convert work center run time load to a labor load. **Default value**: 1	Quantity	

Table 6.46: Capacity (Mfg) fields

Field name	Description	Data type	Key
LaborSetupRatio	The number of hours of labor required for one standard hour of setup. This factor is used to convert work center setup time load to a labor load. **Default value**: 1	Quantity	
MachineRun Ratio	The number of hours of machine time required for one standard hour of run time. This factor is used to convert work center run time load to a machine load. **Default value**: 1	Quantity	
MachineSetup Ratio	The number of hours of machine time required for one standard hour of setup. This factor is used to convert work center setup time load to a machine load.	Quantity	
Maximum Labor Capacity	The maximum number of standard labor hours possible for the work center. **Default value**: 0	Quantity	
Maximum Machine Capacity	The maximum number of standard labor hours possible for the work center. **Default value**: 0	Quantity	
NumberOf Resources	The number of resources available at this work center. Available capacity at the work center is adjusted using this value which must be non-negative. If there are multiple resources available and lot splitting is allowed on a given operation (set by **CRPOperation.MaximumResources**), then the operation will finish quicker than it would if only one resource were used. **Default value**: 0	Quantity	
QueueTime	Pre-operation queue time used for scheduling all operations for this work center unless overridden (see **CRPOperation.QueueTimeOverride**). This value is the number of hours to wait before setup can begin and must be greater than or equal to zero. **Default value**: 0	Quantity	
Utilization	The factor used to scale operation setup and run times for this work center to allow for non-productive periods in the day (for example, breaks). When multiplied with the Efficiency factor, the resulting value is the usage factor. This is used for converting the run time and setup time from "standard hours" to real elapsed hours. **Default value**: 1	Quantity	

Table 6.46: Capacity (Mfg) fields

Field name	Description	Data type	Key
WaitTime	The post-operation wait time used for scheduling all operations for this work center unless overridden (see Operation.WaitTimeOverride). The number of hours to wait after run time processing ends and must be greater than or equal to zero. **Default value**: 0	Quantity	
WorkCenter	Name of the work center. **Referenced table:** WorkCenter	Reference	

CapacityOverride table

The **CapacityOverride** table is used to define work center capacity (such as, working hours, efficiency, number of resources) by specific day of the week. If a work center has one or more effective records defined in this table for a given day of the week, then the record(s) for that day of the week override the work center's standard **Capacity** record. For days of the week on which a work center does not have an effective record in this table, capacity is taken from the **Capacity** table (assuming the work center has a record defined there).

Table 6.47: CapacityOverride (Mfg) fields

Field name	Description	Data type	Key
DayOfWeek	The day of the week to the which the work center capacity details in this record apply. Valid values are: • Monday • Tuesday • Wednesday • Thursday • Friday • Saturday • Sunday If necessary, each work center can have multiple effective records for a given day of the week. For example, each record might represent a different shift in the day with its own working hours, resources, efficiency, and utilization. When taken together, these records would give total work center capacity for the day. If setting up capacity in this manner, ensure to provide an **Index** value for each record. **Note:** Capacity overrides only apply to days within the work center's working calendar.	String (Enum)	
Description	An optional description for this capacity record.	String	

Table 6.47: CapacityOverride (Mfg) fields

Field name	Description	Data type	Key
EffectiveInDate	The date on which the capacity details on this record becomes effective. The record is then effective until the next **EffectiveInDate** found on a record for the same work center, day of the week, and Index.	Date	
Efficiency	The factor used to scale operation setup and run times for this work center. In other words, a measurement of what can hypothetically be produced versus what is actually produced. When multiplied with the **Utilization** factor, the resulting value is the usage factor. This is used for converting the run time and setup time from "standard hours" to real elapsed hours. **Default value:** 1	Quantity	
Id	A string identifier for this capacity record. Along with the **WorkCenter** reference, this field uniquely identifies each capacity record in this table.	String	Yes
Index	An index value for this record. If there are multiple records having the same **EffectiveInDate**, **DayOfWeek**, and **WorkCenter**, then a different index value should be assigned to each record. For example, the index might refer to a specific shift in the day. Note if the same index value is assigned to multiple records having the same **EffectiveInDate**, **DayOfWeek**, and **WorkCenter**, only one of those records will contribute to work center capacity (the others will be ignored).	Integer	
NumberOf Resources	The number of resources available at the work center on the specified day of the week. Available capacity at a work center is adjusted using this value which must be a non-negative number. If there are multiple resources available and lot splitting is allowed on a given operation (set by **CRPOperation.MaximumResources**), then the operation will should quicker than it would if only one resource were used. **Default value:** 0	Quantity	
Utilization	The factor used to scale operation setup and run times for this work center to allow for non-productive periods in the day (for example, breaks). When multiplied by the Efficiency factor, the resulting value is the usage factor. This is used for converting the run time and setup time from "standard hours" to real elapsed hours. **Default value:** 1	Quantity	

Table 6.47: CapacityOverride (Mfg) fields

Field name	Description	Data type	Key
WorkCenter	The name of the work center whose capacity is defined for the day of the week on this record. **Referenced table:** WorkCenter	Reference	Yes
WorkingHour	Number of working hours for this day of the week and work center. **Default value:** 0	Quantity	

Carrier table

The **Carrier** table contains the names of carriers that are either transporting shipments from suppliers or transporting finished goods to customer receiving locations.

Table 6.48: Carrier (Mfg) fields

Field name	Description	Data type	Key
DefaultTransit Time	Default transit time to be applied to customer delivery routes that use this carrier. If the **TransitTime** field on a given **DeliveryRoute** record is non-negative, then that transit time value is used instead.	Quantity	
Default Transportation Mode	The default mode of transportation to be assumed for customer delivery routes that use this carrier. If the **TransportationMode** reference on a given **DeliveryRoute** record that uses this carrier is populated, then that referenced transportation mode is assumed instead. **Referenced table:** TransportationMode (Nullable)	Reference	
Description	A description of this carrier.	String	
LogisticsLocation	Logistics location used by this carrier. **Referenced table**: LogisticsLocation (Nullable) This field was added in Version 2016.2, Service Update 9.	Reference	
TransitCalendar	A reference to the calendar defining transit dates for delivery routes that use this carrier. This calendar thereby determines how planned receipt dates and available receipt dates on **IndependentDemand** records are calculated from the due and available date, respectively. If this reference is Null, then an Everyday calendar is assumed. **Referenced table:** Calendar (Nullable)	Reference	
Value	A unique identifier associated with this carrier.	String	Yes

Carrier table – calculated and set fields

The following describes the calculated and set fields in the **Carrier** table. For an introduction to this table, and descriptions of its input fields, see "Carrier table" on page 238.

Table 6.49: Calculated Carrier (Mfg) fields

Field name	Description	Data type	Key
DeliveryRoutes	Set of delivery routes, used to fulfill customer orders, that use this carrier.	Set	
Shipments	Set of supply orders, shipped from a supplier, that use this carrier.	Set	
Sources	Set of supply sources associated with this carrier.	Set	

CausalFactor table

This table stores causal factors used to adjust historical data for data errors or unusual demand events before a statistical forecast is generated. It references the part customer and historical actual the causal factor applies to (through the **HistoricalDemandHeader** reference), as well as the category the causal factor is associated with (through the **CausalFactorCategory** reference). Additional details of the causal factor, such as the adjustment quantity and date, are stored in the **CausalFactorDetail** table which references this table.

The **CausalFactor** table supports Sales and Operations Planning in RapidResponse. Values in this table are maintained through the **S&OP Data Cleansing** workbook in RapidResponse. For more information about causal factors, see the *RapidResponse Applications Guide*.

Table 6.50: CausalFactor (Mfg) fields

Field name	Description	Data type	Key
Category	A reference to the category this causal factor applies to. **Referenced table:** CausalFactorCategory	Reference	Yes
Description	A description of this causal factor.	String	
Header	A reference to the part, customer, and historical demand combination this causal factor applies to. **Referenced table:** HistoricalDemandHeader	Reference	Yes

CausalFactor table – calculated and set fields

The following describes the calculated and set fields in the CausalFactor table. For an introduction to this table, and descriptions of its input fields, see "CausalFactor table" on page 239.

Table 6.51: Calculated CausalFactor (Mfg) fields

Field name	Description	Data type	Key
Details	Set of causal factor details associated with this CausalFactor record.	Set	

CausalFactorCategory table

This table stores categories defined in your company for grouping causal factors. For example, causal factor categories might include things such as promotions and weather events.

The CausalFactorCategory table supports Sales and Operations Planning in RapidResponse. Values in this table should be configured during initial RapidResponse deployment.

Table 6.52: CausalFactorCategory (Mfg) fields

Field name	Description	Data type	Key
Description	A description of this causal factor category.	String	
ProcessingRule	Indicates whether the causal factor details associated with the causal factor category should be included in S&OP analytics calculations, inventory planning and optimization (safety stock) calculations, or both. Valid values are: • **SOP**—Indicates that causal factor details should be included in S&OP calculations only. For example, they would be used when calculating the statistical forecast or when disaggregating the forecast. • **SafetyStock**—Indicates that the causal factor details should be included in safety stock calculations only. This value is used when outlier adjustments have been created at the part level. • **All**—Indicates that causal factor details should be included in both S&OP and safety stock calculations. This is the default value.	String (Enum)	
Value	A unique identifier (name) for this causal factor category.	String	Yes

CausalFactorCategory table – calculated and set fields

The following describes the calculated and set fields in the CausalFactorCategory table. For an introduction to this table, and descriptions of its input fields, see "CausalFactorCategory table" on page 240.

Table 6.53: Calculated CausalFactorCategory (Mfg) fields

Field name	Description	Data type	Key
CausalFactors	Set of causal factors associated with this CausalFactorCategory record.	Set	

CausalFactorDetail table

This table includes date and quantity details that belong to a given causal factor through the reference to the **CausalFactor** table. In addition, the quantities reported in this table are reflected in disaggregated forecast details and disaggregation rates. If causal details are reported, they are taken into account in the following tables:

- ForecastDetail
- StatisticalForecastDetail
- DisaggregationRateByPartCustomer
- StatisticalForecastDisaggregationRate

The **CausalFactorDetail** table supports Sales and Operations Planning in RapidResponse. Values in this table are maintained through the **S&OP Data Cleansing** workbook in RapidResponse. For more information about causal factors, see the *RapidResponse Applications Guide*.

Table 6.54: CausalFactorDetail (Mfg) fields

Field name	Description	Data type	Key
Date	The date the causal factor is to be applied.	Date	
Factor	A reference to the causal factor the details in this record apply to. **Referenced table**: CausalFactor	Reference	Yes
Id	A unique identifier for this record.	String	Yes
Quantity	The quantity of the causal factor to be applied.	Quantity	
UnitPrice	An optional field allowing a unit price to be applied to the causal factor. If a positive value is not provided in this field, then the unit price for the causal factor is calculated and reported in the EffectiveUnitPrice field. By default, this field is set to -1.	Money	

CausalFactorDetail table – calculated and set fields

The following describes the calculated and set fields in the CausalFactorDetail table. For an introduction to this table, and descriptions of its input fields, see "CausalFactorDetail table" on page 241.

Table 6.55: CausalFactorDetail (Mfg) fields

Field name	Description	Data type	Key
EffectiveUnit Price	The effective unit price for this causal factor. If a positive value is provided in the UnitPrice field, then that value is provided here. Otherwise, this field is calculated as follows: • RapidResponse checks the **CustomerPrice** table for records with matching Part and Customer values that have effective dates less than or equal to the date of this record. If any matching records are found, then the UnitPrice from the record with the latest effective date is reported here. Note that if multiple records exist for a given part and customer combination with the same effective date, the EffectiveUnitPrice calculation uses the record with the larger value in the **CustomerPrice.Id** field. • However, if no matching Part and Customer values are found, RapidResponse next checks the CustomerPrice table for records with a matching Part and blank Customer value (that is, ' ') that have effective dates less than or equal to the record date. If any matching records are found, then the UnitPrice from the record with the latest effective date is reported here. • Finally, if no unit price can be found under any of the conditions mentioned above or if the value provided in **CustomerPrice.UnitPrice** is negative, the value in **Part.AverageSellingPrice** is reported here. However, if the value in **Part.AverageSellingPrice** is also negative, then **CausalFactorDetail.EffectiveUnit Price** is set to zero. Currency conversions on this field use the **Date** field's conversion rate.	Money	

Class table

The **Class** table defines part classes. This table is used to define standard part classes (finished goods, work in progress, and raw materials) and custom classes, such as consumables. These part classes are used to assign planning, safety stock, and replenishment strategies. Part classes are also used in some widgets on the Inventory Manager application dashboard and as standard filters in worksheets.

Table 6.56: Class (Solutions) fields

Field name	Description	Data type	Key
Description	A description of this part class.	String	
Value	The name of the part class.	String	Yes
Parts	The set of parts that belong to this class. **Referenced table:** Part	Set	

Cluster table

The **Cluster** table contains the clusters reported by the Machine Learning service for the Self-Healing Supply Chain. A **Cluster** contains a group of **ItemSource** records with similar lead time properties. For more information about the properties associated with a **Cluster**, see the "ClusterProperty table" on page 244.

This table was added in Version 2016.2, Service Update 21.

Table 6.57: Cluster (Mfg) fields

Field name	Description	Data type	Key
Name	The name of the **Cluster**.	String	Yes
SelfHealingParameter	A parameter to support different use cases for healing planning parameters, such as LeadTime or Yield.	String	Yes
Zone	A parameter passed to the Machine Learning server that is used to generate clusters specific to each zone. The Zone value is calculated for historical data based on the settings defined in the AutomatedLeadTimeType and AutomatedYieldType.	String	Yes

Cluster table – calculated and set fields

The following describes the calculated and set fields in the **Cluster** table.

Table 6.58: Clustercalculated (Mfg) fields

Field name	Description	Data type	Key
ClusterProperties	Set of **ClusterProperty** records that reference this **Cluster**. **Referenced table:** "ClusterProperty table" on page 244	Set	
ItemSources	Set of **ItemSource** records that reference this **Cluster**. **Referenced table:** "ItemSource table" on page 379	Set	

ClusterProperty table

The **ClusterProperty** table contains the properties and values for a particular **Cluster** that is reported by the Machine Learning server for the Self-Healing Supply Chain. A **Cluster** contains a group of **ItemSource** records with similar lead time or yield properties.

This table was added in Version 2016.2, Service Update 21.

Table 6.59: ClusterProperty (Mfg) fields

Field name	Description	Data type	Key
Cluster	The **Cluster** of which this is a property. **Referenced table:** Cluster **Reference syntax:** Cluster.Name, Cluster.SelfHealingParameter	Reference	Yes

Property	The property name. Reported values are:
	• **Site** —The part site for the ItemSource.
	• **Supplier** —The supplier for the ItemSource.
	• **To** —The region of the part site (the destination site) for the ItemSource.
	• **From** —The region of the supplier site for the ItemSource.
	• **By** —The transportation mode for the ItemSource.
	• **Trend** —Whether the planning parameters (such as lead time) for the ItemSource are trending upward, downward, or whether they are flat.
	  • If the slope of linear regression is above a threshold, then the Trend is labeled Upward.
	  • If the slope of linear regression is below a threshold, then the Trend is labeled Downward.
	  • Otherwise, the Trend is labeled Flat.
	• **Seasonality** —Whether the planning parameters for the ItemSource are seasonal or not.
		String	Yes

Table 6.59: ClusterProperty (Mfg) fields

Field name	Description	Data type	Key
ValueBoolean	The value for the boolean property. Valid values are: • **Y** • **N** **Default value:** N	Boolean	
ValueQuantity	The value for the quantity property.	Quantity	
ValueText	The value for the text property.	String	
ValueType	The type for the cluster property values. Valid values are: • **Text** • **Boolean** • **Quantity**	Enum	

CollaborativeForecast table

The CollaborativeForecast table stores forecast information including data provided from suppliers.

Table 6.60: CollaborativeForecast (Mfg) fields

Field name	Description	Data type	Key
BucketDate	The bucketed date of the forecast.	Date	
CommitQty	The quantity committed by the subscriber.	Quantity	
LastCommitted	The date/time of last commit made by the subscriber.	DateTime	
LastUpdated	The date/time of last change made by the customer.	DateTime	
Part	This field is a reference to the Part table. **Referenced table:** Part	Reference	
RequestQty	The quantity requested by the customer.	Quantity	
Response Provided	Specifies if a response was provided from the supplier. Valid values are: • Y • N	Boolean	

Table 6.60: CollaborativeForecast (Mfg) fields

Field name	Description	Data type	Key
Response Required	Specifies if a response is required from the supplier. Valid values are: • Y • N	Boolean	
Source	This field is a reference to the Source table. **Referenced table:** Source	Reference	
State	Supports forecast-collaboration. Valid values are: • InfoOnly • NeedCommit • Committed	String (Enum)	

ConsensusForecastRollingHorizon table

The **ConsensusForecastRollingHorizon** table stores records for defining the order and the duration of the horizon used for applying rolling forecast weights to individual forecast categories when creating the consensus demand plan. This table is referenced by the "ConsensusForecastRollingHorizonWeight table" on page 971, which reports the weight that is applied to a forecast category in a given horizon.

The **ConsensusForecastRollingHorizon** table supports the Demand Planning application in RapidResponse. Values in this table are maintained using the both the **Control Tables** and **S&OP Demand Planning Ratios** workbooks in RapidResponse. For more information about the Demand Planning application, see the RapidResponse Applications Guide.

This table was added in Version 2016.2, Service Update 12.

Table 6.61: ConsensusForecastRollingHorizon (Mfg) fields

Field name	Description	Data type	Key
SequenceId	A value that determines the order in which the duration of a **ConsensusForecastWeight** is applied to the forecast category or header when generating the consensus forecast. The sequence begins at the **SOPAnalyticsConfiguration.CalcForecastStartDate**.	Integer	Yes
Duration	A value that specifies the length of the horizon in which to use the **ConsensusForecastWeight** that is applied to the forecast category or header when generating the consensus forecast. The duration is based on the calendar specified by **SOPAnalyticsConfiguration.CycleCalendar**. If a duration value is less or equal to zero (<=0), it is ignored.	Integer	

ConsensusForecastRollingHorizon table – calculated and set fields

The following describes the set fields in the **ConsensusForecastRollingHorizon** table.

Table 6.62: ConsensusForecastRollingHorizon (Mfg) set fields

Field name	Description	Data type	Key
CategoryWeights	Set of **HistoricalDemandCategoryRollingWeight** records associated with a given horizon.	Set	
HeaderWeights	Set of **HistoricalDemandHeaderRollingWeight** records associated with a given horizon.	Set	

Constraint table

The Constraint table lists all available constraints used by RapidResponse.

Table 6.63: Constraint (Mfg) fields

Field name	Description	Data type	Key
Calendar	The calendar to use when allocating constraint to load. **Referenced table:** Calendar	Reference	
ConstraintGroup	A reference to the group, if any, this constraint belongs to. Groups of related constraints are often managed together based on key work function and/or the planner responsible for them. **Referenced table**: ConstraintGroup (nullable)	Reference	
CumulativeMax	The total amount of this constraint that remains available to all supplies (contract maximum). Regardless of effective dates, the constraint is no longer available after the CumulativeMax has been used up. If CumulativeMax <= 0, it is ignored.	Quantity	
DataDate	Defines the current Constraint period. No Constraint is available in periods before the one containing this date. DataDate is also used as MRP Run Date when defining Constraint Manager bucket ranges. **Referenced table:** Calendar **Reference Syntax:** DataDate.Value	Reference	
Description	A description of the constraint.	String	

Table 6.63: Constraint (Mfg) fields

Field name	Description	Data type	Key
KeyConstraint	Indicates if the constraint is a key constraint. To identify the constraints that are important to your organization, you should set them as key constraints. For example, the constraints that are key to your organization's planning process. This field is in the **Solutions** namespace. **Default value:** N	Boolean	
Name	The identifier for the constraint. Typical identifiers include: • Part number • Supplier + Part number • Bottleneck resource name • Assembly line or production area • Supplier + part family	String	Yes
PlannerCode	A reference to the planner responsible for this constraint. **Referenced table:** PlannerCode (Nullable)	Reference	
Site	The site associated with this constraint. Choose one site to own all common external constraints and the None constraint. **Referenced table:** Site	Reference	Yes
Type	A value that is associated with processing rules that defines the constraint's behavior. **Referenced table:** ConstraintType	Reference	
UnitOfMeasure	The units in which this constraint is measured. Not used for any conversion. (Use SourceConstraint.ConstraintFactor and PartSource.SupplierUOM to handle any conversions). **Referenced table:** ConstraintUnitOfMeasure	Reference	
UsedThisPeriod	Adjusts constraint available for the first (current) period. The amount of constraint that has been consumed, in the Constraint.Calendar period containing DataDate, by supplies that are not in the current data set. (Values <=0 are ignored). **Note:** UsedThisPeriod does not affect CumulativeMax calculations.	Quantity	

Constraint table – calculated and set fields

The following describes the calculated and set fields in the Constraint table. For an introduction to this table, and descriptions of its input fields, see "Constraint table" on page 247.

Table 6.64: Calculated Constraint (Mfg) fields

Field name	Description	Data type	Key
IsRecursive	In versions of RapidResponse prior to 8.2.1, this field was used to indicate if a constraint was involved in a recursive relationship (**Y** or **N**). As of Version 8.2.1, this field is obsolete and always reports a value of **N** as multi-level constraints are now supported. For more information, see "Planning with multi-level constraints" on page 1644.	Boolean	
AssumptionBy Constraints	Set of AssumptionbyConstraint records.	Set	
Constraint Availables	Time-phased availability of this Constraint.	Set	
ConstraintLoads	Set of calculated ConstraintLoad records.	Set	
Constraint SpreadLoads	Set of calculated ConstraintSpreadLoad records.	Set	
ConstraintUseds	Set of calculated ConstraintUsed records.	Set	
FLPConstraints	Set of calculated FLPConstraint records.	Set	
PeriodLoads	Set of calculated PeriodConstraintLoad records.	Set	
SourceConstraints	Set of SourceConstraint records.	Set	

ConstraintAvailable table

This table supports the Constraint Manager application, and is used to define the availability (rate) of a constraint over a period of time.

Two calculated fields on this table report the first and last effective dates for a record based on the input dates provided as well as calendar and control settings.

Table 6.65: ConstraintAvailable (Mfg) fields

Field name	Description	Data type	Key
Constraint	The constraint this availability applies to. **Referenced table:** Constraint **Reference Syntax:** Constraint.Name, Constraint.Site	Reference	
EffectiveInDate	The date when this record becomes effective (subject to the **ConstraintType.EffectivityRule**). Use "Past" if the constraint is available before the beginning of the calendar. **NOTE**: If this date is not aligned to a date on the constraint calendar (**Constraint.Calendar**), then calendar rounding occurs and results might not be as expected. For example, assume the default **ConstraintType.EffectvityRule** of "InclusiveExclusive". If the constraint calendar is "Month" and the **EffectiveInDate** is "05/16/2018", the record is effective from the beginning of May.	Date	
EffectiveOutDate	The date when this record is no longer effective (subject to the **ConstraintType.EffectivityRule** setting). Use "Future" if the Constraint is available through the end of the calendar. **NOTE**: If this date is not aligned to a date on the constraint calendar (**Constraint.Calendar**), then calendar rounding occurs and results might not be as expected. For example, assume the default **ConstraintType.EffectvityRule** of "InclusiveExclusive". If the constraint calendar is "Month" and the **EffectiveOutDate** is "07/31/2018", the record stops being effective at the end of June.	Date	
Rate	Amount of constraint available for each time period (Constraint.Calendar) during the effective time of this record. If more than one ConstraintAvailable record is effective for a period, the Rates are added. Rates < 0 are seen as reducing Constraint available over their effective period. A total rate of zero (0) over a period indicates that no Constraint is available during that period (and if the total rate is < 0, then constraint avaialble is reported as 0). Rate is assumed to be defined in terms of the Constraint.UOM, however no conversion is done. Also, any unit of measure can be used for the rate of constraint available. However, all supplies using the constraint should define their constraint usage with the same units.	Quantity	

ConstraintAvailable table – calculated and set fields

The following describes the calculated and set fields in the ConstraintAvailable table. For an introduction to this table, and descriptions of its input fields, see "ConstraintAvailable table" on page 249.

Table 6.66: Calculated ConstraintAvailable (Mfg) fields

Field name	Description	Data type	Key
FirstEffective Date	Date when this ConstraintAvailable record becomes effective. (Undefined if never effective). Calculated as: • Undefined if calculated to be after LastEffectiveDate or if Type.EffectivityRule = 'Never' • Past if Type.EffectivityRule = 'Always' or if EffectiveInDate = 'Undefined' • EffectiveInDate+ 0 Constraint.Calendar If Type.EffectivityRule = 'Inclusive' or 'InclusiveExclusive' • EffectiveInDate + 1 Constraint.Calendar If Type.EffectivityRule = 'Exclusive'	Calculated Date	
LastEffective Date	Last date when this ConstraintAvailable record remains effective. (Undefined if never effective). Calculated as: • Undefined if calculated to be before FirstEffectiveDate or if Type.EffectivityRule=Never • Future if Type.EffectivityRule = 'Always' or if EffectiveOutDate = 'Undefined' • (EffectiveOutDate + 1 Constraint.Calendar)- 1: If Type.EffectivityRule = 'Inclusive' • (EffectiveOutDate + 0 Constraint.Calendar) - 1: If Type.EffectivityRule in (Exclusive, InclusiveExclusive)	Calculated Date	
Overlap	Indicates an anomaly in the ConstraintAvailable records for this Constraint. All ConstraintAvailable records that overlap each other are flagged. Valid values are: • Y • N During the period of overlap, the Rate is seen as the sum of the overlapping Rates.	Boolean	

ConstraintGroup table

The **ConstraintGroup** table is used to group sets of related constraints that should typically be managed together. For example, constraints might be grouped on the basis of key work function or the individual responsible for planning them.

Table 6.67: ConstraintGroup (Mfg) fields

Field name	Description	Data type	Key
Description	A description of this group. Typically, this might indicate the key work function performed by the constraints in this group.	String	
Id	A unique string identifier for this group.	String	Yes

ConstraintGroup table – calculated and set fields

The following describes the calculated and set fields in the ConstraintGroup table. For an introduction to this table, and descriptions of its input fields, see "ConstraintGroup table" on page 251.

Table 6.68: Calculated ConstraintGroup (Mfg) fields

Field name	Description	Data type	Key
Constraints	Set of constraints that belong to this group.	Set	

ConstraintMetric table

The **ConstraintMetric** table identifies the combination for each constraint and metric definition generated for a specific as of date that are used in live lens and comparison scorecards.

This table was added in Version 2016.2, Service Update 19.

Table 6.69: ConstraintMetric (Solutions) fields

Field name	Description	Data type	Key
AsOf	The date on which the constraint and metric definitions are generated. **Referenced table:** MetricAsOf	Reference	Yes
Constraint	A reference to the constraint associated with this combination of constraint and metric definition data. **Referenced table:** Constraint	Reference	Yes
Metric	A reference to the metric associated with this combination of constraint and metric definition data. **Referenced table:** Metric	Reference	Yes

ConstraintMetric table – calculated and set fields

The following describes the calculated and set fields in the ConstraintMetric table. For an introduction to this table, and descriptions of its input fields, see "ConstraintMetric table" on page 252.

Table 6.70: ConstraintMetric (Solutions) fields

Field name	Description	Data type	Key
ConstraintMetricValues	The set of constraint calculations that belong to this combination of constraint and metric definition data. **Referenced table:** ConstraintMetricValues	Set	

ConstraintMetricValues table

The **ConstraintMetricValues** table stores the constraint calculations for metrics used in live lens and comparison scorecards.

This table was added in Version 2016.2, Service Update 19.

Table 6.71: ConstraintMetricValues (Solutions) fields

Field name	Description	Data type	Key
Date	The date associated with this calculation.	Date	Yes
ConstraintMetric	A reference to the constraint and metric definition combination associated with this calculation. **Referenced table:** ConstraintMetric	Reference	Yes
Quantity	The quantity for the metric. The value in this field is used if Metric.ValueType= 'Quantity'. For more information, see "Metric table" on page 399.	Quantity	
Value	The money value for the metric. The value in this field is used if Metric.ValueType= 'Money'. For more information, see "Metric table" on page 399.	Value	

ControlSet table

This table holds all control sets defined in your RapidResponse system. Each control set is comprised of all entries in other tables that point to that record's Value field. The tables that reference the ControlSet table include the Site table and a large number of control tables; for a full listing of these tables, see "ControlSet table — calculated and set fields" on page 254.

Control sets allow for the same control table value to potentially have different meanings across RapidResponse sites. For example, a PartType value of "P" may indicate a purchased part in the control set associated with one site, and a phantom part in the control set associated with another site. Control sets can also be used to hold all expected characteristics for a particular type of RapidResponse installation within your demand or supply network. The control set can then be exported, imported, and otherwise manipulated across sites as needed. For complete information on managing controls sets, see the *RapidResponse Administration Guide*.

Table 6.72: ControlSet (Core) fields

Field name	Description	Data type	Key
Value	A unique identifier for this control set.	String	Yes
Description	A description of this control set.	String	

Note: For more information on control sets, see "Control sets" on page 161.

ControlSet table – calculated and set fields

The following describes the calculated and set fields in the Control Set table. Each field represents the set of records on another table that references the Control Set table. For an introduction to this table, and descriptions of its input fields, see "ControlSet table" on page 253.

Table 6.73: Calculated ControlSet (Core) fields

Field name	Description	Data type	Key
Allotment Override Types	The set of values in the AllotmentOverrideType table associated with this control set.	Set	
AlternatePart Types	The set of values in the AlternatePartType table associated with this control set.	Set	
AvailableRules	The set of values in the AvailableRule table associated with this control set.	Set	
BOMTypes	The set of values in the BOMType table associated with this control set.	Set	
ConstraintTypes	The set of values in the ConstraintType table associated with this control set.	Set	
ConstraintUnitOf Measures	The set of values in the ConstraintUnitOfMeasure table associated with this control set.	Set	
CRPUnitOf Measures	The set of values in the CRPUnitOfMeasure table associated with this control set.	Set	
DemandStatuses	The set of values in the DemandStatus table associated with this control set.	Set	
DemandTypes	The set of values in the DemandType table associated with this control set.	Set	
ForecastItem ParametersTypes	The set of values in the ForecastItemParametersType table associated with this control set.	Set	
IncrementalRules	The set of values in the IncrementalRule table associated with this control set.	Set	

Table 6.73: Calculated ControlSet (Core) fields

Field name	Description	Data type	Key
InventoryTransfer Types	The set of values in the IncrementalTransferType table associated with this control set.	Set	
MEIOLeadTime Types	The set of values in the MEIOLeadTimeType table associated with this control set.	Set	
MUEPoolNetting Types	The set of values in the MUEPoolNettingType table associated with this control set.	Set	
OnHandTypes	The set of values in the OnHandType table associated with this control set.	Set	
OperationTypes	The set of values in the OperationType table associated with this control set.	Set	
OrderPolicies	The set of values in the OrderPolicy table associated with this control set.	Set	
OrderPriorities	The set of values in the OrderPriority table associated with this control set.	Set	
PartSourceTypes	The set of values in the PartSourceType table associated with this control set.	Set	
PartTypes	The set of values in the PartType table associated with this control set.	Set	
ProjectTypes	The set of values in the ProjectType table associated with this control set.	Set	
RangeOf Coverages	The set of values in the RangeOfCoverage table associated with this control set.	Set	
ResourceTypes	The set of values in the ResourceType table associated with this control set.	Set	
Shipment Policies	The set of values in the ShipmentPolicy table associated with this control set.	Set	
Sites	The set of values in the Site table associated with this control set.	Set	

Table 6.73: Calculated ControlSet (Core) fields

Field name	Description	Data type	Key
SourceRules	The set of SourceRule records associated with this control set.	Set	
SpreadProfiles	The set of SpreadProfile records associated with this control set.	Set	
SubstituteGroup Types	The set of SubstituteGroupType records associated with this control set.	Set	
SupplyAllocation Types	The set of SupplyAllocationType records associated with this control set.	Set	
SupplyStatuses	The set of SupplyStatus records associated with this control set.	Set	
TaskTypes	The set of TaskType records associated with this control set.	Set	
ToleranceProfiles	The set of ToleranceProfile records associated with this control set.	Set	
ToleranceProfile Zones	The set of ToleranceProfileZone records associated with this control set.	Set	
SupplyTypes	The set of SupplyType records associated with this control set.	Set	
UnitOfMeasures	The set of UnitOfMeasure records associated with this control set.	Set	
WorkCenterTypes	The set of WorkCenterType records associated with this control set.	Set	

CRPOperation table

The **CRPOperation** table identifies operations required in the production of a part. Each operation is identified by an Id along with the supply routing and sequence it belongs to and work center it uses. Additional operation details such as the duration of each phase of an operation and the sequence in which the operations should occur should also be provided.

Prior to Version 2014.4, operations were defined in the **Operation** table. Any resources (such as, workbooks) based on that table will continue to function, however the **CRPOperation** table should be used for new purposes.

Table 6.74: CRPOperation (Mfg) fields

Field name	Description	Data type	Key
BatchQuantity	The batch quantity for this operation. This represents the number of units per supply that the operation must complete before it can be passed on the next operation for processing. If set to 0 (zero), then the entire operation must be completed before the supply can be sent to the next operation in the sequence. When the current operation produces supply in batches, the next operation in the sequence may be able to begin processing the supply once it receives a batch. However, if that next operation's batch size is greater than that of the current operation, it must further wait until it has received enough supply to also satisfy its own batch quantity. **Default value:** 0 **Note:** The **Type.BatchQuantityRule** control setting provides further control over how a value of 0 (zero) is used in determining when an operation can begin processing batched supply from the previous operation in the sequence. For more information about working with batches, see "Overlapping operations" on page 1527.	Quantity	
Description	A description of this operation.	String	
EffectiveInDate	The date this record becomes effective. The effectivity of each operation in a routing is determined based on the start date of the work order (scheduled receipt or planned order). That is, the entire sequence of operations is determined from the start of the order. **Default value:** Undefined	Date	
EffectiveOutDate	The date this record expires. The effectivity of each operation in a routing is determined based on the start date of the work order (scheduled receipt or planned order). That is, the entire sequence of operations is determined from the start of the order. **Default value:** Undefined	Date	
EndUnit	The end of the unit range to which this operation record applies. The end unit is either included in the range or excluded depending upon the values in **OperationType.EffectivityRule** and **OperationType.DependentUnitRule**. This field is ignored unless MUERule is Unit or ModelUnit. Every supply will be seen as being before EndUnit if EndUnit is <0. **Default value:** -1	Integer	

Table 6.74: CRPOperation (Mfg) fields

Field name	Description	Data type	Key
Id	A string identifier for this operation. Together with the Sequence and WorkCenter reference fields, this value uniquely identifies an operation. Typically, it might be set to the operation number.	String	Yes
Maximum Resources	Indicates the maximum number of work center resources that can concurrently work on this operation. If it is possible to split the operation between resources, then the operation should finish sooner. The lesser of this value and the available number of resources at the work center is used to determine the actual number of resources applied to the operation. **Default value:** 0	Quantity	
Model	The model to which this operation applies. The values in this field is ignored unless the referenced **Type.MUERule** value is either "ModelUnit" or "Unit". **Referenced table:** Model (Nullable)	Reference	
Number	The operation number. This value is used for scheduling operations that belong to the same sequence. Operations with lower numbers are scheduled first. If multiple effective operations in a sequence have the same number, the following fields are used to determine scheduling order: • WorkCenter.Name (alphabetical sort) • EffectiveInDate (earliest first) **Default value:** 0	Integer	
QueueTime Override	Optionally, used to specify the number of hours to wait before operation setup can begin at the work center. If this field is left negative, then the **QueueTime** value specified on the **Capacity** record applicable to the work center is used. Otherwise, if this value is greater than or equal to zero, it overrides the **QueueTime** value. **Default value:** -1	Quantity	
RunTime	Specifies the amount of time required for this operation to run through or process one unit of an order. This value is adjusted by **RunTimeUOM** and multiplied by the order quantity to get the total run time in hours for a given order. **Default value:** 0	Quantity	

Table 6.74: CRPOperation (Mfg) fields

Field name	Description	Data type	Key
RunTimeUOM	The run time unit of measure for this operation. Used to convert the specified run time into standard hours per piece. **Referenced table:** CRPUnitOfMeasure	Reference	
Sequence	A reference to the specific sequence within the routing this operation belongs to. An operation can belong to the routing's standard sequence, of which there should be exactly one, or any of its optional parallel sequences. **Referenced table:** OperationSequence **Reference Syntax**: Sequence.Id, Sequence.Routing.Id	Reference	Yes
SetupHours	The number of standard hours required to set up one machine for use in this operation. **Default value:** 0	Quantity	
StartUnit	The beginning of the unit range to which this operation record applies. The start unit is either included or excluded in the range depending on the settings in **Type.EffectivityRule** and **Type.DependentUnitRule**. Every supply will be seen as being after StartUnit if StartUnit is <0. This field is ignored unless **Type.MUERule** is set to either "Unit" or "ModelUnit". **Default value:** -1	Integer	
TearDownTime	Indicates the amount of tear down time (in hours) required after this operation has completed processing. This is the time used to remove parts and restore the work center to its normal state in preparation for the next order. **Default value:** 0	Quantity	
TransitTime	Indicates the amount of time needed to move between operations. If **Type.TransitTimeSequenceRule** is "AfterOperation", this represents the time to move from this operation to the next one in the sequence. If **Type.TransitTimeSequenceRule** is "BeforeOperation", this represents the time to move from the previous operation in the sequence to this one. This value should be expressed in either hours (by default) or days as determined by the setting in **Type.TransitTimeProcessingRule.** **Default value:** 0	Quantity	

Table 6.74: CRPOperation (Mfg) fields

Field name	Description	Data type	Key
Type	A reference to the control value that defines processing rules for this operation such as how effectivity is determined. **Referenced table:** OperationType	Reference	
WaitTimeOverride	Optionally, used to specify the number of hours of waiting time after the operation run has completed at the work center. If this field is left negative, then the **WaitTime** value specified on the **Capacity** record applicable to the work center is used. Otherwise, if this value is greater than or equal to zero, it overrides the **WaitTime** value. **Default value:** -1	Quantity	
WorkCenter	The name of the work center where this operation is performed. **Referenced table:** WorkCenter	Reference	

CRPOperation table – calculated and set fields

The following describes the calculated and set fields in the **CRPOperation** table. For an introduction to this table, and descriptions of its input fields, see "CRPOperation table" on page 256.

Table 6.75: Calculated CRPOperation (Mfg) fields

Field name	Description	Data type	Key
Allocations	Set of Allocation records that reference this record.	Set	
BOMs	Set of BillOfMaterial records that reference this record.	Set	
CRPOperation States	Set of CRPOperationState records that reference this record.	Set	

CRPOperationState table

The **CRPOperationState** table can be used to identify a scheduled receipt that has been partially completed by a given work center operation in its routing. Each record in this table references both a **ScheduledReceipt** record and a **CRPOperation** record, and also contains a **CompleteQty** field used to indicate how much of the receipt has already been processed by the referenced operation. This allows Capacity Requirements Planning calculations to start processing an ongoing scheduled receipt at an operation other than the first one in its routing and/or to only schedule that operation for the portion of the order has yet to be completed.

This table also contains fields used to indicate the date and time at which an ongoing operation starts a particular phase. Typically, the start date for the current phase of the ongoing progress operation should be provided. However, if multiple phase start dates are defined, then the latest of those phases is used to represent the ongoing state of the operation and the earlier phases are assumed to be completed.

The **CRPOperationState** table was added in Version 2014.4

Table 6.76: CRPOperationState (Mfg) fields

Field name	Description	Data type	Key
ActualFinishDate	The date on which the operation actually finished processing this order. This field is optional and should typically only be used if maintaining historical operation data. Providing a date in this field implies that the operation has already finished processing this order (regardless of any values provided in the **CompleteQty** field). Note also that any provided date in this field is assumed to represent the start of the available working hours for the day unless an offset is given in **ActualFinishOffset**. **Default value**: 0	Date	
ActualFinish Offset	The number of hours into the available hours per day at which the operation finished processing this order. **Default value:** 0	Quantity	
ActualProcess StartDate	The date on which the operation starts processing the order (beginning of the run time phase). This is assumed be the start of the available working hours for the day unless an offset is specified in **ActualProcessStartOffset**. **Default value:** Undefined	Date	
ActualProcess StartOffset	The number of hours into the available hours per day at which work center processing starts for the remainder of this operation. **Default value:** 0	Quantity	
ActualSetup StartDate	The date on which the setup phase begins for this operation. This is assumed to be the start of the available working time for the day unless an offset is specified in **ActualSetupStartOffset**. **Default value:** Undefined	Date	
ActualSetup StartOffset	The number of hours into the available hours per day at which work center setup began for this operation. **Default value:** 0	Quantity	

Table 6.76: CRPOperationState (Mfg) fields

Field name	Description	Data type	Key
ActualStartDate	The date on which the overall operation starts. This is assumed to be the start of the available working hours for the day unless an offset is specified in **ActualStartOffset**. **Default value:** Undefined	Date	
ActualStartOffset	The number of hours into the available hours per day at which work center tear down began for this operation. **Default value:** 0	Quantity	
ActualTearDown StartDate	The actual date on which work center tear down starts for this operation. This is assumed to be the start of the available working hours for the day unless an offset is specified in **ActualTearDownStartOffset**. **Default value:** 0	Date	
ActualTearDown StartOffset	The number of hours into the available hours per day at which work center tear down starts for this operation. **Default value:** 0	Quantity	
CompleteQty	For partially completed operations, this indicates the amount of the order that has already been processed. Note that when batch processing is enabled, this should specify the total amount of the order that the operation has processed across all batches. The difference between the value in this field and the order quantity is the remaining amount still be processed by the operation. If there is an amount still to be processed, then load is generated from the operation starting on the date defined in one of the following fields: **Default value:** 0	Integer	
CRPOperation	A reference to the work center operation being run for the supply identified on this record. When parallel operations are enabled, a single scheduled receipt might reference multiple parallel operations. However, if multiple operations within the same sequence are configured as partially complete for a given scheduled receipt, then the latest non-batched operation in the sequence is assumed to be ongoing and all operations before it are assumed to be finished. **Referenced table:** CRPOperation **Reference Syntax**: **Reference Syntax**: CRPOperation.Id, CRPOperation.Sequence.Id, CRPOperation.Sequence.Routing.Id, CRPOperation.Sequence.Routing.Site.	Reference	Yes

Table 6.76: CRPOperationState (Mfg) fields

Field name	Description	Data type	Key
Scheduled Receipt	A reference to the supply being processed by the work center operation identified on this record. **Referenced table:** ScheduledReceipt **Reference Syntax**: ScheduledReceipt.Line, ScheduledReceipt.Order.Type, ScheduledReceipt.Order.ID, ScheduledReceipt.Order.Site	Reference	Yes

CurrencyConversionForecast table

Contains forecasted currency conversion rates. The records in this table represent conversion rates that will be used as of the specified date. The rates in this table are combined with the **CurrencyConversionActual** and **HistoricalCurrencyConversion** tables to determine the rates used to perform currency conversions. The date specified for the conversion determines which conversion rate is used. For example, the rates in this table are used as conversion rates only if the specified conversion date is later than the current date.

This table is in the Core namespace.

Table 6.77: CurrencyConversionForecast (Core) fields

Field name	Description	Data type	Key
Currency	The currency type. **Referenced table**: Currency	Reference	
Date	The date the conversion rate is calculated for.	Date	
Rate	The conversion rate as of the specified date.	Quantity	

For more information, see "HistoricalCurrencyConversion table " on page 324 and "CurrencyConversionActual table" on page 1276.

CurveParameters table

This table is used by the Event Management analytic when calculating the adjustments for an event phase that has its **ActionType** set to "Curve." The type of curve, specified in this table's **Type** field, determines the formula used to define the shape of the curve.

In the context of the following field descriptions, `time` is the number of dates on **EventPhase.Calendar** since the beginning of the event phase.

For more information, see "Using curves to adjust the forecast" on page 2116.

This table was added in Version 2016.2, Service Update 3.

Table 6.78: CurveParameters (Mfg) table

Field name	Description	Type	Key
ExponentialRate	The base of the exponent in the formula: `InitialValue * ExponentialRate`^{time} This value cannot be negative. If a negative value is specified, it is treated as zero. Only used when "ExponentialCurve" is specified in the **Type** field. **Default value:** 0	Quantity	
Id	The unique identifier for the set of curve parameters defined in this record.	String	Yes
ImitationRate	The proportion of imitators in the populations of consumers. This value must fall between zero and 1. Negative numbers are treated as zero and numbers greater than one are treated as one. Only used when "DiffusionCurve" is specified in the **Type** field. **Default value:** 0	Quantity	
InitialValue	The first point on the curve at time t=0 for all types of curves. **Default value:** 0	Quantity	
InnovationRate	The proportion of innovators in the population of consumers. This value must fall between zero and 1. Negative numbers are treated as zero and numbers greater than one are treated as one. If a value greater than zero is not specified, the curve is flat. Only used when "DiffusionCurve" is specified in the **Type** field. **Default value:** 0	Quantity	
LinearRate	The slope of the linear curve, used in the formula: `InitialValue + LinearRate * time` Only used when "LinearCurve" is specified in the **Type** field. **Default value:** 0	Quantity	
MaximumValue	The maximum value for the Bass Diffusion Curve. If this value is equal to or less than the InitialValue, the curve is flat. Only used when "DiffusionCurve" is specified in the **Type** field. **Default value:** equal to InitialValue	Quantity	

Table 6.78: CurveParameters (Mfg) table

Field name	Description	Type	Key
Type	The type of curve defined in this record. Determines how the shape of the curve is calculated. Valid values are: • **LinearCurve** Use a linear curve (straight line with a defined slope). • **ExponentialCurve** Use an exponential curve. • **DiffusionCurve** Use Bass Diffusion Model curve to model behavior of consumers. **Default value:** LinearCurve	String (Enum)	
UnitOfMeasure	The unit of measure that this CurveParameters record is associated with. **Referenced table:** UnitOfMeasure	Reference	

CurveParameters table – calculated and set fields

The following describes the set field in the CurveParameters table. For an introduction to this table, and descriptions of its input fields, see "CurveParameters table" on page 263.

Table 6.79: CurveParameters (Mfg) fields

Field name	Description	Data type	Key
EventPhases	The EventPhase records that use this set of curve parameters.	Set	

CurvePoint table

The **CurvePoint** table contains the individual point values that make up the efficiency curves associated with each named value in the **PointsCurve** table. The resulting curves can be used by tasks that have a **TaskType.EfficiencyCurveRule** of "PointsCurve" in order to define a varying efficiency of resources assigned to those tasks and hence impact the calculated task durations.

Besides a reference to the relevant PointsCurve value, each value in this table also contains Index and Quantity values. The Index defines the particular point on the curve and typically corresponds to a day on the task, and the Quantity defines the efficiency of resources on the task at for that point or day.

For example, assume the following set of index and quantity values referencing a given curve YZ, and further assume a single resource assigned to a task using that curve and on an 8 hour work day.

Curve	Index	Quantity
YZ	1	.25
YZ	2	.25

Curve	Index	Quantity
YZ	3	.5
YZ	4	1

With these curve values, 2 hours would be achieved towards completion of the task on the first day, 2 hours again on the second day, 4 hours on the third day, and 8 hours on the fourth and all subsequent days. Thus, a task that would take a resource 4 days to complete if no efficiency curve were used, would take the same resource 6 days to complete if using the YZ curve.

This table's records can be edited using the **Efficiency Curves** worksheet included with the **Project Master Data** workbook in RapidResponse.

Table 6.80: CurvePoint (ProjMgmt) fields

Field name	Description	Data type	Key
Curve	A reference to the named points curve this point belongs to. Each value in this table that references a given PointsCurve defines the full set of points on that curve. **Referenced table:** PointsCurve	Reference	Yes
Id	A unique string identifier for this point.	String	Yes
Index	The position on the curve that the point value specified in the Quantity field applies to. For example, 1 is the first point on the curve, 2 is the second point on the curve, and so on. Typically, these values align to resource work days on the task.	Integer	
Quantity	The point value (resource efficiency) for the position on the curve specified in the Index field. Typically, values greater than zero (0) and less than or equal to one (1) are specified. For example, a value of .4 implies resource efficiency of 40% at a given point on the curve. Note that any points after the last point on a curve inherit their Quantity value from that last entry. As well, any negative or zero values are interpreted to mean one (1).	Quantity	

Customer table

A customer is a consumer of an independent demand item and may be a consumer, a distributor, service center, or a plant identifier for inter-plant orders.

This table's **Site** field is optional, and a system or data administrator can choose whether it uniquely identifies records in the table, or is ignored in queries, and not shown in insert definitions, dialog boxes, or the Data Sources and Mapping window.

Table 6.81: Customer (Mfg) fields

Field name	Description	Data type	Key
CustomerGroup	The group this customer is in. **Referenced table**: CustomerGroup (this reference is nullable in new installations of RapidResponse 10.1 and later).	Reference	
CustomerService Representative	Identifies the customer service representative responsible for this customer. **Referenced table:** PlannerCode (Nullable) **Note:** This field is in the **Solutions** namespace.	Reference	
EarlyShipWindow	Maximum number of days earlier than needed that orders for the customer are allowed to ship. For example, shipping an order early might allow for early revenue recognition. Shipping their orders any earlier than the amount of time specified here requires explicit customer contact and approval. This field supports the order fulfillment application and should be expressed in terms of the Everyday calendar**.** It acts as a default early ship window for all of the customer's orders, but can be overridden on individual demands by providing a positive **EarlyShipWindow** value on the **IndependentDemandSolution** record. **Note:** This field is in the Solutions namespace.	Integer	
HoldCode	The default hold code, if any, that is currently assigned to the customer's orders. Hold codes can be used to prevent orders from moving past a particular stage of processing. For example, if a customer has exceeded their credit limit, a credit hold might be placed on their orders to prevent shipment. **Referenced table:** HoldCode (Nullable) **Note:** This field is in the Solutions namespace. Note also that hold codes can also be associated with individual line items (on **IndependentDemandSolution** records) which then take precedence over any hold code specified for the customer.	Reference	
Id	A value that identifies the customer. **Default value**: Undefined	String	Yes

Table 6.81: Customer (Mfg) fields

Field name	Description	Data type	Key
KeyCustomer	Indicates whether or not this customer is considered a key (important) customer. This field is used in certain metrics supporting the Order Fulfillment application to enable metric values that are calculated for both all customers as well as key customers only. Valid values are: • **N**—this is not considered a key customer. • **Y**—this is considered a key customer. **Note:** This field is in the Solutions namespace.	Boolean	
Name	The name of the customer. **Default value**: blank string	String	
Region	The name of the region associated with this supplier. For example, this might identify the sales territory associated with this customer. **Referenced table:** Region (Nullable)	Reference	
Site	The site associated with this customer record. This field is optional. **Referenced table:** Site	Reference	Yes

For more information about making the **Site** field optional, see "Modifying table and field properties" in the *RapidResponse Data Integration Guide*.

Customer table – calculated and fields

The following describes the calculated and set fields in the Customer table. For an introduction to this table, and descriptions of its input fields, see "Customer table" on page 266.

Table 6.82: Calculated Customer (Mfg) fields

Field name	Description	Data type	Key
Orders	Set of DemandOrder records for existing orders from this customer.	Set	
Projects	Set of Project records for projects associated with this customer.	Set	

CustomerDestination table

The **CustomerDestination** table identifies the specific locations where customers receive delivery of their orders. For example, a record in this table might identify a given customer warehouse or store along with contact information for that location.

Table 6.83: CustomerDestination (Mfg) fields

Field name	Description	Data type	Key
Address	A street address for this customer destination. If this table is used to support maps, the address in this field determines the geocode that is used to mark the destination's location on the map. To ensure that the correct geocode is used, follow the guidelines outlined in "Using address data to support maps" on page 1735.	String	
ContactName	The name of the key contact at this customer destination.	String	
Customer	A reference to the customer associated with the receiving destination described on this record. **Referenced table:** Customer **Reference Syntax:** Customer.Id, Customer.Site	Reference	Yes
DefaultRoute	The default delivery route that is typically used to send deliveries to this customer destination.	String	
Description	An optional description of the customer destination described on this record.	String	
Email	An email address associated with a contact at this customer destination.	String	
Id	A unique string identifier for this customer destination.	String	Yes
Phone	Telephone number used to make contact with this customer destination.	String	
DeliveryRoutes	Set of delivery routes that serve this customer destination.	Set	

CustomerGroup table

The CustomerGroup table defines groups that different customers can be placed under. If your company's host system uses more than one name to refer to the same company, they can be placed in the same group, and the group name used to refer to the entire company.

Table 6.84: CustomerGroup (Mfg) fields

Field name	Description	Data type	Key
Id	The group name.	String	Yes
Description	A description of this group. This can be the company name or a general classification for several different companies.	String	

CustomerGroup table – calculated and set fields

The following describes the calculated and set fields in the CustomerGroup table.

Table 6.85: Calculated CustomerGroup (Mfg) fields

Field name	Description	Data type	Key
Customers	The customers in this group.	Set	

CustomerPrice table

The CustomerPrice table stores time-phased pricing details. It allows for different unit prices to be specified over time for given part and customer combinations. Various tables that report **EffectiveUnitPrice** fields, such as the **ForecastDetail** table, make use of this table when calculating the price to use for a part and customer combination on a given date.

Table 6.86: CustomerPrice (Mfg) fields

Field name	Description	Data type	Key
Customer	The customer associated with this customer price record. A blank (' ') value indicates this is the "default" customer used when an effective entry for a given part and customer combination cannot be found. **Referenced table**: Customer **Reference Syntax:** Customer.Id, Customer.Site	Reference	Yes
EffectiveDate	The date the unit price takes effect for this customer and part combination.	Date	
Id	A value that uniquely identifies this record. If multiple records exist for a given part and customer combination with the same effective date, the **EffectiveUnitPrice** calculation uses the record with the larger value in this field.	String	Yes

Table 6.86: CustomerPrice (Mfg) fields

Field name	Description	Data type	Key
Part	The part associated with this customer price record. **Referenced table**: Part **Reference Syntax**: Part.Name, Part.Site	Reference	Yes
UnitPrice	The unit price that takes effect for this customer and part combination on the effective date.	Money	

DeliveryRoute table

The **DeliveryRoute** table is used to model the different routes for shipping finished goods to customer destinations. For example, the expected shipping time required for an order to move from the order site to the customer's receiving location is specified here.

Many of the fields in this table are is used in calculations determining the planned ship and customer receipt dates on IndependentDemand records, as well as the available ship and customer receipt dates on those records.

Table 6.87: DeliveryRoute (Mfg) fields

Field name	Description	Data type	Key
Carrier	The carrier being used to transport goods along this route to the customer. **Referenced table:** Carrier	Reference	
DefaultPickPack Time	The amount of time required to pull an order from inventory at the site and prepare it for shipment along the route to the customer. Note that if the **PickPackTime** field on the **Part** record has a positive value, then it is used instead of the value provided here.	Integer	
Description	Description of this delivery route.	String	
Destination	The customer location that is receiving the order. **Referenced table:** CustomerDestination	Reference	Yes
EstimatedCost	An estimate of the cost associated with using this delivery route to ship an order (can be used to express relative costs between delivery routes).	Money	

Table 6.87: DeliveryRoute (Mfg) fields

Field name	Description	Data type	Key
Id	A unique string identifier for this delivery route. For example, this might be a concatenation of the Carrier and TransportationMode values or some other string that uniquely identifies a route between the ShipFrom site and customer destination.	String	Yes
PickupCalendar	A reference to the calendar that defines the dates on which orders can be shipped from this site. **Referenced table:** Calendar	Reference	
ShipFrom	The site from which the order is being shipped to the customer. This should resolve to the same site as referenced from **IndependentDemand.Part.Site**. **Referenced table**: Site	Reference	Yes
TransitTime	The amount of time a shipment using this route is expected to take to reach the customer. This value should be expressed in units of the **Carrier.TransitCalendar**. If that reference is Null, then an Everyday calendar is assumed. **Note:** If this field is set to a negative value, then the value from **Carrier.DefaultTransitTime** is used.	Integer	
Transportation Mode	Indicates the mode of transportation associated with this route. For example, land, air, or sea. **Referenced table**: TransportationMode	Reference	
Independent Demands	Set of independent demands using delivery route to reach the customer receiving location.	Set	

DemandOrder table

The **DemandOrder** table contains all common (header) information for **IndependentDemand** records. Header information is common information about an entire order.

Table 6.88: DemandOrder (Mfg) fields

Field name	Description	Data type	Key
Customer	The customer of the order. **Referenced table:** Customer **Reference Syntax:** Customer.Id, Customer.Site	Reference	
Id	A value that identifies an order number for an IndependentDemand record. **Default value**: blank string	String	Yes
Pool	The pool to which this demand order belongs. For example, this might typically refer to a pool specific to the customer the order is for. This field supports inventory pooling as well as forecast consumption by pool. It is only applicable to parts who use a **MUEPoolNettingType.PoolRule** setting other than "Ignore". If any line items under the order have their **InputPool** reference populated, then that referenced pool is used instead. Typically, this is done when pools do not correspond to items associated with demand orders. For example, if pools are meant to represent specific plants or storage locations, rather than customers, then pool values should typically be specified on **IndependentDemand** records. **Referenced table**: Pool **Reference Syntax:** Pool.Value	Reference	
Site	The site this demand order relates to. **Referenced table:** Site	Reference	Yes
Type	A value that determines the processing policies of demand. **Referenced table:** DemandType	Reference	Yes

DemandOrder table – calculated and set fields

The following describes the calculated and set fields in the DemandOrder table. For an introduction to this table, and descriptions of its input fields, see "DemandOrder table " on page 272.

Table 6.89: Calculated DemandOrder (Mfg) fields

Field name	Description	Data type	Key
Lines	Set of line items (IndependentDemand records) for this order.	Set	

Department table

The Department table identifies the department of a work center. A department is generally a group of related WorkCenters.

This table's **Site** field is optional, and a system or data administrator can choose whether it uniquely identifies records in the table, or is ignored in queries, and not shown in insert definitions, dialog boxes, or the Data Sources and Mapping window.

Table 6.90: Department (Mfg) fields

Field name	Description	Data type	Key
Id	Name for the department. It must be unique. **Default value**: blank string	String	Yes
Site	The site where this department is located. This field is optional. **Referenced table:** Site	Reference	Yes

For more information about making the **Site** field optional, see "Modifying table and field properties" in the *RapidResponse Administration Guide*

Department table—calculated and set fields

The following describes the calculated and set fields in the Department table. For an introduction to this table, and descriptions of its input fields, see "Department table" on page 274.

Field name	Description	Data Type	Key
CustomerOrders	Set of CustomerOrder records that reference this Department value.	Set	

EngineeringChange table

The EngineeringChange table identifies engineering changes. Engineering changes (EC) are referenced by BillOfMaterial records to identify sets of records that are associated with a common change.

Field name	Description	Data type	Key
Analysis Parameters	Parameters used in the analysis of the engineering change. This field is populated automatically when simulating an engineering change, and should be left blank.	String	
Description	A description of the change. String	String	
Id	Identifier for the change. **Default value**: blank string	String	Yes
Originator	The name of the person that originated the change.	String	
Reason	The motivation for creating the change. For example, reduction in cost, product improvement, or an introduction of a new product.	String	
Site	The RapidResponse site. This is applicable only if the change applies to a single site.	String	
Type	The type of change, such as 'ECO', 'Deviation', or 'Stop Ship'.	String	

EngineeringChange table–calculated and set fields

The following describes the calculated and set fields in the EngineeringChange table. For an introduction to this table, and descriptions of its input fields, see "EngineeringChange table" on page 274.

Field name	Description	Data type	Key
BOMIn	Set of BillOfMaterial records introduced by this EC.	Set	
BOMOut	Set of BillOfMaterial records made obsolete by this EC.	Set	
Notes	Collaborative notes related to the change. This field can used to enter notes about an engineering change. Each time a note value is added to this field through a worksheet, a new record is created in the EngineeringChange_Notes table with a date and timestamp, user ID, note text, and a reference to the EngineeringChange record against which it was created. **Referenced table:** EngineeringChange_Notes	Note	

Event table

The Event table is used to group related event phases, which are used by the Event Management analytic to make forecast adjustments. This table is used for reference, to help organize and keep track of event phases. Two event phases in the EventPhase table can have the same name and adjustment type, as long as they belong to different events.

The data in this table do not affect the analytic calculations, apart from helping to distinguish one event phase from another. For more information, see "Event Management" on page 2109.

This table was added in Version 2016.2, Service Update 3.

Table 6.91: Event (Mfg) fields

Field name	Description	Data type	Key
CreationDate	Date when the event was created.	Date	
Description	A description of the event	String	
Name	The name of the event	String	Key
PlannerCode	The planner code associated with the event **Referenced table:** PlannerCode	Reference	
Type	The event type. **Referenced table:** EventType	Reference	

Event table – calculated and set fields

The following describes the set field in the Event table. For an introduction to this table, and descriptions of its input fields, see "Event table" on page 276.

Table 6.92:

Field name	Description	Data type	Key
EventPhases	The EventPhase records associated with this event	Set	

EventPhase table

This table is used by the Event Management analytic. An **EventPhase** record contains information including when the phase begins and ends, the calendar used, and how the forecast should be adjusted during that phase.

For more information, see "Event Management" on page 2109.

This table was added in Version 2016.2, Service Update 3.

Table 6.93: EventPhase (Mfg) fields

Field name	Description	Data type	Key
Adjustement Type	The aspect of the forecast to adjust. Valid values are: • Quantity • UnitPrice **Default value:** Quantity	Enum	Yes
ActionType	The type of action that will be taken to adjust the forecast. For more information, see "Action types for event phases" on page 2110. Valid values are: • **Quantity** Add the value in the Quantity field to the original forecast. • **CompoundedQuantity** Adjust the forecast by compound increments of the value in the **Quantity** field. • **Percentage** Increase the original forecast by the percentage specified in the **Percent** field. • **Compounded Percentage** Adjust the forecast by compound increments of the percent value in the **Percent** field. • **Constant** Replace original forecast with the value in the **Quantity** field. • **Curve** Use a curve to determine forecast adjustments. The **CurveParameters** field determines which set of curve parameters to use. **Default value:** Quantity	Enum	
Calendar	Calendar to be used when applying the adjustment. Input parameters, such as **Quantity**, **Percent,** and **CurveParameters**, are specified in terms of this calendar. Input data is bucketed using this calendar before the adjustment is applied. **Referenced table:** Calendar	Reference	
Category	The EventPhase applies to HistoricalDemandHeaders whose category matches the category referenced by this field. This field is nullable. If the field is null, the EventPhase applies to all associated HistoricalDemandHeaders **Referenced table:** HistoricalDemandCategory	Reference	
Compounding Calendar	Calendar used to determine compounding intervals within compounding buckets. This field is nullable. If a valid value is not specified, the Everyday calendar is used. Single date calendars, such as RunDate, are not valid in this field. **Referenced table:** Calendar	Reference	

Table 6.93: EventPhase (Mfg) fields

Field name	Description	Data type	Key
CompoundingIntervalCount	The number of intervals in a single compounding bucket. If a negative value is specified, it is treated a 1. **Default value:** 1	Integer	
CreationDate	The date when the **EventPhase** was created. This is an optional value that can be used for reference. It is not used for analytic calculations.	Date	
CurveParameters	The set of curve parameters to use. This value is only relevant if **ActionType** is set to "Curve." This field is nullable. **Referenced table:** CurveParameters **Default value:** null	Reference	
Description	A description of the event phase.	String	
EndDate	First date (after the **StartDate**) to which this **EventPhase** does not apply.	Date	
Event	The **Event** that this **EventPhase** is associated with. **Referenced table:** Event	Reference	Yes
Name	The name of the event phase	String	Yes
Percent	Used to determine the percent to adjust the forecast by when **ActionType** is set to "Percentage" or "CompoundedPercentage." To specify 100%, enter `100` in this field. **Default value:** 0	Quantity	
Quantity	Used to determine the quantity of forecast adjustments when **ActionType** is set to "Quantity," "CompoundedQuantity," or "Constant." **Default value:** 0	Quantity	
StartDate	First date to which this EventPhase applies.	Date	
UsageRule	An EventPhase is only applied if this field is set to "Use." To prevent an EventPhase from affecting the forecast without deleting the EventPhase, set this field to "Ignore." Valid values include: • Use • Ignore **Default value:** Use	String (Enum)	

EventPhase table – calculated and set fields

The following describes the calculated and set fields in the Model table. For an introduction to this table, and descriptions of its input fields, see "EventPhase table" on page 276.

Table 6.94: Calculated EventPhase (Mfg) fields

Field name	Description	Data type	Key
FirstEffective Date	First effective date for this EventPhase. This is a date on the calendar specified in the **Calendar** field. It falls on or after the **StartDate**. For more information, see "Determining the effective dates and date buckets for an event phase" on page 2125.	Date	
LastEffective Date	Last effective date for this EventPhase. This is a date on the calendar specified in the **Calendar** field. It falls before the **EndDate**. For more information, see "Determining the effective dates and date buckets for an event phase" on page 2125.	Date	
Event Disaggregation Rates	The EventDisaggretationRate records associated with this EventPhase.	Set	
EventPhase Headers	The EventPhaseHeader records associated with this EventPhase. EventPhaseHeader records connect EventPhase records with HistoricalDemandHeader records.	Set	
EventStatistical Disaggregation Rates	The EventStatisticalDisaggregationRates records associated with this Eventphase.	Set	

EventPhaseHeader table

This table supports the Event Management analytic. The **EventPhaseHeader** table connects **EventPhase** records with records on the **HistoricalDemandHeader** table, which identifies each unique part, customer, and historical demand category combination. For more information, see "Connecting event phases to the affected forecast" on page 2112.

This table was added in Version 2016.2, Service Update 3.

Table 6.95: EventPhaseHeader (Mfg) fields

Field name	Description	Data type	Key
EventPhase	An EventPhase **Referenced table:** EventPhase	Reference	Yes
Header	The HistoricalDemandHeader record that defines the portion of the forecast the event phase is applied to. **Referenced table:** HistoricalDemandHeader	Reference	Yes
Id	It is recommended that this field be left blank unless you are using attribute-based planning. For more information about attribute-based planning, see "Attribute-based planning" on page 1817. If you are using attribute-based planning you might need to enter a unique identifier in this field to distinguish EventPhaseHeader records applicable to data with different attributes for the same HistoricalDemandHeader and EventPhase combination.	String	Yes

EventType table

The EventType table is used to categorize events. This table is used for reference, to help organize and keep track of events. Values in this table do not affect analytic functionality.

This table was added in Version 2016.2, Service Update 3.

Table 6.96: EventType (Mfg) fields.

Field name	Description	Data type	Key
Description	Description of the event type.	String	
Value	Name of the event type.	String	Yes

EventType table – calculated and set fields

The following describes the set field in the EventType table. For an introduction to this table, and descriptions of its input fields, see "EventType table" on page 280.

Table 6.97: EventType (Mfg) fields

Field name	Description	Data type	Key
Events	The Event records associated with this EventType.	Set	

Feature table

The **Feature** table holds all features that has been defined in RapidResponse. Each feature represents a particular option on a configurable end-item assembly. For example, a feature might refer to a particular engine model or a set of tires that go into an automobile.

If using feature BOM logic in RapidResponse, a list of features can be specified on a demand using the **IndependentDemand.FeatureList** field. This list is then compared against rules defined in the **BillOfMaterial.FeatureRule** field to determine which of an assembly's components are required in a supply being built to satisfy that demand.

Note that feature values can be specified on **IndependentDemand** and **BillOfMaterial** records without having been defined in the this table. However, it is recommended to ensure that all applicable feature values are added to the **Feature** table. This provides a reference for all features, allows for features values to be mapped together in the **FeatureMap** table, and ensures that certain calculated tables are able to reference and report details for all active features.

Table 6.98: Feature (Mfg) fields

Field name	Description	Data type	Key
Description	A description of the feature.	String	
Value	A unique name or identifier for the feature.	String	Yes

Feature table – calculated and fields

The following describes the calculated and set fields in the Feature table. For an introduction to this table, and descriptions of its input fields, see "Feature table" on page 281.

Table 6.99: Calculated Feature (Mfg) fields

Field name	Description	Data type	Key
ToFeatures	Set of FeatureMap records that reference this value.	Set	

FeatureMap table

The **FeatureMap** table is used to setup feature values expected to be inputted on assembly's demands and map or expand them to larger groups of features. When a demand matches a feature value set up in this table, all of its mapped features are then used for comparison against BOM records to determine which of the assembly's components should have dependent demands placed on them.

Each record in this table identifies the assembly part the record pertains to, along with a **FromRule** field used to specify a feature or feature rule to compare against feature lists on independent demands, and a **ToFeature** field that references a feature in the **Feature** table. If the feature list on a demand matches a given **FromRule** value, then all corresponding **ToFeature** references are used in determining effective features for the demand.

Typically, each **FromRule** value associated with an assembly should be associated with multiple **ToFeature** values. For example, suppose the following set of records.

Part	FromRule	ToFeature
Auto1	AA	Y1
Auto1	AA	Y2
Auto1	AA	Y3

This would indicate that if a demand for part "Auto1" contains the feature "AA" in its feature list, then features "Y1", "Y2", and "Y3" apply to the demand and components of "Auto1" corresponding to these features are required in supply built to satisfy the demand.

Table 6.100: FeatureMap (Mfg) fields

Field name	Description	Data type	Key
BaseKey	A unique string identifier for this record.	String	Yes
EffectiveInDate	The date on which this record becomes effective. This allows for feature mappings that change over time.	Date	
EffectiveOut Date	The date on which this record is no longer effective. This allows for feature mappings that change over time.	Date	
FromRule	The feature value being mapped by this record. When a feature specified on an assembly demand in the **IndependentDemand.FeatureList** field matches the value specified here, then that input feature is expanded to mean all features referenced through the **ToFeature** field for this value. This expanded feature list is then compared against values in the **BillOfMaterial.FeatureRule** field in order to determine which of the assembly's components that dependent demands should be placed on. This field can contain either a single feature name or it can contain a more complex feature rule using any of the following logical operators: • **And**—used to indicate multiple features that must all be specified on the demand for this rule to be considered a match. By default, an ampersand symbol (&) is used for "and". For example, *a1 & b2*. • **Or**—used to indicate multiple features any one (or more) of which must be present on the demand for this rule to be considered a match. A comma (,) is used to represent "or" and the specified features should also be enclosed in parentheses. For example, *(a1, a2, a3)*. • **Not**—used to indicate features that must not be present on the assembly demand for the rule to be considered a match. For example, *! b2*.	String	

Table 6.100: FeatureMap (Mfg) fields

Field name	Description	Data type	Key
Part	The assembly part whose demands this feature map is used for. **Referenced table**: Part	Reference	
Sequence	The order in which expansion of mapped features occurs. The order can be important for specifying situations where a given FromRule relies on previously mapped feature expansions in this table. **Default value:** 0	Integer	
ToFeature	Reference to a particular feature that the value or rule provided in the **FromRule** field should map to. All values referenced through this field for a given **FromRule** value together comprise the expanded feature list. **Referenced table:** Feature	Reference	

ForecastDetail table

This table holds current forecast data at the detail level (after any disaggregation calculations have been performed). Each record pertains to a given part, customer, and category combination, and shows details such as the forecast quantity and date. Different types of forecasts can be stored in this table such as the statistical forecast, sales forecast, marketing forecast, and so on.

The **ForecastDetail** table supports Sales and Operations Planning in RapidResponse. The values shown in this table are based on aggregate values entered or maintained through various resources in RapidResponse. For example, details of the statistical forecast are based on values generated by the **Save Forecast** command in the **S&OP Statistical Forecast** workbook. Details of other types of forecast are based on values entered in workbooks belonging to the related constituent group (for example, values might be provided through the **S&OP Marketing Forecast** workbook, **S&OP Sales Forecast** workbook, **S&OP Finance Operating Plan** workbook, and so on). The values in this table also reflect any causal quantities that are reported in the **CausalFactorDetail** table.

This table contains vector set data for records in the **HistoricalDemandHeader** table. For more information about vectors, see "Vector data" on page 138.

If you have upgraded from RapidResponse 2014.2 (or earlier) to RapidResponse 2014.4 (or later) and your company has not converted the five standard tables to contain vector data, the following differences exist in this table:

- The Date field is not a key field.
- The Header field is a reference, not an owning reference.

You can determine whether this table is using vector data by opening the Data Model dialog box and reviewing table icons. Tables that contain vector data are displayed with the icon.

Table 6.101: ForecastDetail (Mfg) fields

Field name	Description	Data type	Key
Date	The date of this forecast item.	Date	Yes
ID	An identifier for this forecast record.	String	Yes
Header	A reference to the historical demand header associated with the record. This identifies the part customer and demand category for this forecast. **Referenced table**: HistoricalDemandHeader **Reference Syntax**: Header.PartCustomer.Part.Name, Header.PartCustomer.Part.Site, Header.Category	Reference (Owning)	Yes
ProtectQuantity	Indicates whether the value in the Quantity field is modified when data is edited in a grouped worksheet. This field is used in the Advanced Data Editing dialog box as part of the expression that determines which records are not edited when a grouped worksheet is edited. Valid values are: • **Y**—the Quantity cannot be modified in summarized worksheets. • **N**—the Quantity can be modified. For more information, see "Protect a record" in the *RapidResponse Resource Authoring Guide*. **Default value**: N	Boolean	
Quantity	The amount of this forecast. The value in this field is used if the header's **HistoricalDemandCategoryType.UnitType = 'Quantity'**. For more information, see "HistoricalDemandCategory table" on page 329.	Quantity	
UnitPrice	Allows for a unique unit price to be specified for this forecast order. For example, this might be used to reflect the price effective during a sales promotion. If a non-negative value is provided here, it is always reported in the **EffectiveUnitPrice** field (typically used for revenue calculations). If a negative value is provided here, the unit price is calculated based on matching records in the **CustomerPrice** or **Part** tables. For more information, see EffectiveUnitPrice Default value: -1	Quantity	
Value	The total revenue target for this forecast. The value in this field is used if the header's **HistoricalDemandCategory.Type.UnitType = 'Value'**. For more information, see "HistoricalDemandCategoryType table" on page 736.	Money	

Notes:

- If a historical record of all forecast detail items in this table is required, then a process should be set up to archive data from this table into the **HistoricalDemandSeries** and **HistoricalDemandSeriesDetail** tables.
- Consensus forecast values calculated based on weighted combinations of different streams of forecast data in this table can be seen in the **ConsensusForecast** table, and are utilized elsewhere by RapidResponse analytics. For more information, see "ConsensusForecast table" on page 966.

ForecastDetail table – calculated fields

The following describes the calculated fields in the ForecastDetail table. For an introduction to this table, see "ForecastDetail table" on page 283.

Table 6.102: ForecastDetail calculated (Mfg) fields

Field name	Description	Data type	Key
EffectiveUnit Price	The effective unit price for this forecast order. This value is based on either the input unit price provided on this record or else the unit price effective for the forecast's part and customer (as defined through the Header field reference) on the date of this record. This value is useful when calculating revenue, and is calculated as follows: • If a non-negative value is provided in the **UnitPrice** field, then it is always used. • Otherwise, RapidResponse checks the **CustomerPrice** table for records with matching Part and Customer values that have effective dates less than or equal to the date of this record. If any matching records are found, then the **UnitPrice** from the record with the latest effective date is reported here. Note that if multiple records exist for a given part and customer combination with the same effective date, record with the larger value in the **CustomerPrice.Id** field is used. • However, if no matching Part and Customer values are found, RapidResponse next checks the **CustomerPrice** table for records with a matching Part and blank Customer value (that is, ' ') that have effective dates less than or equal to the record date. If any matching records are found, then the UnitPrice from the record with the latest effective date is reported here. • Finally, if no unit price can be found under any of the conditions mentioned above or if the value provided in **CustomerPrice.UnitPrice** is negative, then the value in **Part.AverageSellingPrice** is reported here. However, if the value in **Part.AverageSellingPrice** is also negative, then **ForecastDetail.EffectiveUnit Price** is set to zero. Currency conversions on this field use the **Date** field's conversion rate.	Money	

Table 6.102: ForecastDetail calculated (Mfg) fields

Field name	Description	Data type	Key
ToleranceProfile Zone	A calculated reference to the tolerance profile zone to be used for evaluating whether changes to forecast details are inside or outside of tolerance. To choose a tolerance profile zone, this field first calculates the number of ToleranceCalendar intervals between the Date on this ForecastDetail record and the part's planning date as follows: `Date - Header.PartCustomer.Part.PlanningCalendars.RunDate.FirstDate Header.PartCustomer.ToleranceProfile.ToleranceCalendar` For the applicable tolerance profile, the ToleranceProfileZone record with the ZoneEndInterval field value that is nearest to and greater than the result of the calculation shown above is chosen. If no ToleranceProfileZone record meets this condition, the reference is Null. **Referenced table:** ToleranceProfileZone	Reference	

ForecastDisaggregationParameters table

This table holds parameter values at the part-customer and forecast category level that are used to override the default parameters set by the **SOPAnalyticsConfiguration** table when determining disaggregation rates.

The **ForecastDisaggregationParameters** table supports Sales and Operations Planning in RapidResponse. Values in this table are maintained using the **S&OP Forecast Disaggregation** workbook in RapidResponse. For more information about forecast disaggregation, see the *RapidResponse Applications Guide*.

Notes:

- If the same disaggregation parameters should apply to all part-customers for a given forecast category, then override parameters can be specified on a record in the **ForecastDisaggregationParametersByCategory** table instead.
- Calculated disaggregation rates, whether based on the values in this table or other tables, can also be overridden for a given part customer and forecast category combination by providing override date and quantity (rate) values in the **ForecastDisaggregationOverride** table. For more information, see "ForecastDisaggregationOverride table" on page 290.

Table 6.103: ForecastDisaggregationParameters (Mfg) fields

Field name	Description	Data type	Key
ActualsCategory	A reference to the historical demand actual category used to calculate disaggregation rates for the part customer. **Referenced table:** HistoricalDemandCategory	Reference	
Header	A reference to the part customer and category combination this set of disaggregation parameters applies to. The category reference is used as the forecast category. **Referenced table:** HistoricalDemandHeader	Reference	Yes
HistoricalInterval Count	The number of periods of historical data to use when calculating disaggregation rates for this part customer and forecast category combination.	Integer	
Id	A unique identifier for this record.	String	Yes
InnerCalendar	The inner disaggregation calendar used in forecast disaggregation with seasonal trends to define the length of a season. For example, with season month-in-year disaggregation, this would be set to a monthly calendar. Months with higher values in them would then receive more of the data being disaggregated. If forecast disaggregation is not seasonal, this should be set to the same value as the OuterCalendar. **Referenced table:** Calendar	Reference	
OuterCalendar	The outer disaggregation calendar used in forecast disaggregation to define the period over which a forecast is disaggregated. For example, with season month-in-year disaggregation, this would be set to a yearly calendar. The calendar referenced by this field cannot represent smaller intervals than the one referenced by the InnerCalendar field (it can however be the same calendar if disaggregation is not seasonal). The OuterCalendar marker should also always land directly on the InnerCalendar marker. For example, with month-in-year disaggregation, then the Yearly calendar marker should land on a marker that defines the start of a monthly calendar. **Referenced table:** Calendar	Reference	

ForecastDisaggregationParametersByCategory table

The **ForecastDisaggregationParametersByCategory** table holds parameter values at the forecast category level that are used to override the default parameters set by the **SOPAnalyticsConfiguration** table when determining disaggregation rates. This table is appropriate for use when disaggregation parameters are required that apply to all part customers associated with a particular forecast category.

For example, all part customers associated with a given forecast category might have their disaggregation rates based on the same historical demand category and using the same range of historical data.

The **ForecastDisaggregationParametersByCategory** table supports Sales and Operations Planning in RapidResponse. Values in this table are maintained using the **S&OP Forecast Disaggregation** workbook in RapidResponse. For more information about forecast disaggregation, see the *RapidResponse Applications Guide*.

Notes:

- If parameters need to be overridden for specific part customer and forecast category combinations, the **ForecastDisaggregationParameters** table should be used (values provided in that table take precedence over this one).
- Calculated disaggregation rates, whether based on parameter values in this table or other tables, can also be manually overridden for a given part customer and forecast category combination by providing override date and quantity (rate) values in the **ForecastDisaggregationOverride** table. For more information, see "ForecastDisaggregationOverride table" on page 290.

Table 6.104: ForecastDisaggregationParametersByCategory (Mfg) fields

Field name	Description	Data type	Key
ActualsCategory	A reference to the historical demand actual category used to calculate disaggregation rates for this forecast category. **Referenced table:** HistoricalDemandCategory	Reference	
Category	A reference to the forecast category that the set of disaggregation parameters defined on this record applies to. **Referenced table:** HistoricalDemandCategory	Reference	Yes
HistoricalInterval Count	The number of periods of historical data to use when calculating disaggregation rates for this forecast category.	Integer	
InnerCalendar	The inner disaggregation calendar used in forecast disaggregation with seasonal trends to define the length of a season. For example, with season month-in-year disaggregation, this would be set to a monthly calendar. Months with higher values in them would then receive more of the data being disaggregated. If forecast disaggregation is not seasonal, this should be set to the same value as the OuterCalendar. **Referenced table:** Calendar	Reference	

Table 6.104: ForecastDisaggregationParametersByCategory (Mfg) fields

Field name	Description	Data type	Key
OuterCalendar	The outer disaggregation calendar used in forecast disaggregation to define the period over which a forecast is disaggregated. For example, with season month-in-year disaggregation, this would be set to a yearly calendar. The calendar referenced by this field cannot represent smaller intervals than the one referenced by the InnerCalendar field (it can however be the same calendar if disaggregation is not seasonal). The OuterCalendar marker should also always land directly on the InnerCalendar marker. For example, with month-in-year disaggregation, then the Yearly calendar marker should land on a marker that defines the start of a monthly calendar. **Referenced table:** Calendar	Reference	

ForecastDisaggregationOverride table

This table provides disaggregation rates that override the calculated rates when disaggregating forecasts to the detail level.

If a record exists in this table for a specific part customer and forecast category on a given date, the quantity on that record is used as the effective rate in determining forecast disaggregation for that part customer, category and date. If a record does not exist in this table for a specific part customer and forecast category on a given date, then disaggregation rates are calculated based on the part-customer and forecast category specific parameters provided in the **ForecastDisaggregationParameters** table (if they exist, or else using the default disaggregation parameters for the scenario as specified in the **SOPAnalyticsConfiguration** table).

The **ForecastDisaggregationOverride** table supports Demand Planning in RapidResponse. Values in this table are maintained using the **S&OP Forecast Disaggregation** workbook in RapidResponse. For more information about forecast disaggregation, see the *RapidResponse Applications Guide*.

Notes:

- If the **DisaggregationQuantityRule** field on the **HistoricalDemandCategoryType** table is set to "Actuals", the **ForecastDisaggregationOverride** table can be used to specify rates for a particular part-customer and forecast category on specific dates and these will then be reported in the **DisaggregationRateByPartCustomer** table, rather than calculating them for that part-customer and category on that date.
- If the **DisaggregationQuantityRule** field on the **HistoricalDemandCategoryType** table is set to "ConsensusForecast" for calculating forecast disaggregation rates, the overrides in this table are not used in the **DisaggregationRateByPartCustomer** table.

Table 6.105: ForecastDisaggregationOverride (Mfg) fields

Field name	Description	Data type	Key
Date	The date on which the disaggregation rate becomes effective. The **ForecastDisaggregationOverride.Quantity** value is then considered effective from the specified **Date** until the next **DisaggregationCalendar** marker (at which point another rate override can be provided or else the calculated disaggregation rate will be used). **Note:** For more information about how disaggregation override rates are calculated, see "Override calculated disaggregation rates" on page 2092.	Date	
Header	A reference to the part customer and category combination this set of values applies to. The category reference is used as the forecast category. **Referenced table:** HistoricalDemandHeader	Reference	Yes
Id	A unique identifier for this record.	String	Yes
Quantity	The override quantity for the part customer and forecast category on the specified date. This value represents a rate and not the actual percentage used in disaggregation. For example, suppose the forecast for a given date is being disaggregated between two items X and Y, where X has an override quantity of 600 and Y has an override quantity of 200. The actual percentages used in disaggregation would be 75% on X (600/800) and 25% on Y (200/800).	Quantity	

ForecastDisaggregationOverride calculated fields

The following describes the calculated fields in the ForecastDisaggregationOverride table.

Table 6.106: ForecastDisaggregationOverride calculated (Mfg) fields

Field name	Description	Data type	Key
EffectiveUnit Price	The unit price effective for the forecast's part and customer (as defined through the Header field reference) on the date of this record. This value is useful when calculating revenue, and is calculated as follows: • RapidResponse checks the CustomerPrice table for records with matching Part and Customer values that have effective dates less than or equal to the date of this record. If any matching records are found, then the UnitPrice from the record with the latest effective date is reported here. Note that if multiple records exist for a given part and customer combination with the same effective date, the EffectiveUnitPrice calculation uses the record with the larger value in the CustomerPrice.Id field. • However, if no matching Part and Customer values are found, RapidResponse next checks the CustomerPrice table for records with a matching Part and blank Customer value (that is, ' ') that have effective dates less than or equal to the record date. If any matching records are found, then the UnitPrice from the record with the latest effective date is reported here. • Finally, if no unit price can be found under any of the conditions mentioned above, the value in Part.AverageSellingPrice is reported here. Currency conversions on this field use the **Date** field's conversion rate.	Money	

ForecastItem table

This table is used for the configuration of forecast items for which statistical forecasts can be generated. A record exists for each unique forecast item that has been calculated or configured in RapidResponse. A forecast item is made up of a combination of levels from different hierarchies that are accessible from the PartCustomer table.

The ForecastItem table supports Demand Planning and Statistical Forecasting in RapidResponse. Typically, the values in this table are automatically created based on attributes that are configured on the **PartCustomer** table during a RapidResponse deployment.

Table 6.107: ForecastItem (Mfg) fields

Field name	Description	Data type	Key
FilterExpression	A query filter expression that can be applied to the **PartCustomer** table to find all part customers belonging to this forecast item. **Note:** This field is obsolete	String	
Path	A unique identifier for this record. Each value in this field is a concatenated string consisting of all values that identify the forecast item. For example, it might consist of a part name and customer group.	String	Yes
PathExpression	The query expression that returned the string of values in the Path field at the time this ForecastItem record was created. RapidResponse uses the result of evaluating this expression to compare against the Path field and ensure that part customer are still assigned to the correct forecast item. **Note:** This field is obsolete	String	
PathLevels	A concatenated string of consisting of each levels of the reference path from the PartCustomer table to the value(s) reported in the Path field. **Note:** This field is obsolete (as of Version 2015.3).	String	
UsageRule	Controls whether the statistical forecast is calculated for this forecast item. Valid values are: • **Use**—calculate the statistical forecast for this item. • **Ignore**—do not calculate the statistical forecast for this item.	String (Enum)	

ForecastItem table – calculated and set fields

The following describes the calculated and set fields in the ForecastItem table. For an introduction to this table, and descriptions of its input fields, see "ForecastItem table" on page 292.

Table 6.108: Calculated ForecastItem (Mfg) fields

Field name	Description	Data type	Key
Effective Disaggregation Calendar	The disaggregation calendar used when disaggregating forecast quantities for this part customer. **PartCustomer.DisaggregationCalendar** is used when defined; otherwise, the disaggregation calendar specified in the **SOPAnalyticsConfiguration** table is used for disaggregation **Referenced table:** Calendar	Reference	
Parameters	Set of forecast item parameters associated with this ForecastItem record.	Set	
PartCustomers	Set of part customers associated with this ForecastItem record.	Set	

ForecastItemFitOutput table

This table shows the result of fitting the statistical model for forecast items. This table contains output parameters associated with a particular forecast model along with details generated from fitting the model such as model constants and error measures.

The ForecastItemFitOutput table supports Demand Planning and Statistical Forecasting in RapidResponse. This table is populated by running the **Generate and Save Forecast** command in the **S&OP Forecast Item Configuration** workbook. This table is considered obsolete and the **ForecastItemParametersFitOutput** table should generally be used instead.

Table 6.109: ForecastItemFitOutput (Mfg) fields

Field name	Description	Data type	Key
Class	The type of output parameter being reported in this record. Valid values are: • **DataCharacteristic**—a characteristic of the input data points characteristic. For example, "MeanQty", or "Count". • **ErrorMeasure**—error measure of fitted values against the input data points. For example, "MeanError". • **Message**—message type generated from the statistical models. For example, "Warning" or "Error" • **ModelConstant**—constants used by the model (alpha, beta, gamma, and so on). • **ModelOutput—**output from the statistical model that will be used to generate forecast.	String (Enum)	
ForecastModel	The forecast model used to generate this fitted output. Valid values are: • ARIMA • ARIMAX • BestFit • CrostonsMethod • DoubleExponentialSmoothing • ExponentialSmoothing • Elastic Net • HoltWintersMethod • Linear • MovingAverage • MultipleLinearRegression • StepWiseARIMA **Note:** For more information about these models, see "ForecastModel" on page 731.	String (Enum)	
ItemParameters	A reference to the forecast item parameters this fitted output applies to. The forecast item can also be found through this reference. **Referenced table:** ForecastItemParameters	Reference	Yes
ParameterName	The name of the output parameter. For example, "Error" or "Warning".	String	Yes
ParameterValue	The value associated with the named parameter. For example, this field might contain the description of an error.	String	

ForecastItemParameters table

This table contains input parameters used in generating a statistical forecast for a given forecast item and/or used in generated safety stock recommendations for a given safety stock item. Note that each forecast item can have several statistical forecasts generated, but each must be associated with a different forecast category.

The **ForecastItemParameters** table supports Demand Planning and Statistical Forecasting and Inventory Planning and Optimization in RapidResponse. Most values in this table are maintained through the **S&OP Forecast Item Management** workbook in RapidResponse, and new records are added to the table whenever new **ForecastItem** records are created.

The values in this table that relate to using multiple linear regression models for statistical forecasting, such as **ElasticNetParameter** and **WeightsDecayFactor**, are maintained in the **S&OP Regressor Management** workbook.

For more information, see "Statistical forecasting models" on page 2031.

Table 6.110: ForecastItemParameters (Mfg) fields

Field name	Description	Data type	Key
ActualsCategory	A reference to the historical actual demand category used as input in generating the statistical forecast for the forecast item. Actual demands in this category are adjusted for causal factors and then used as the basis for the statistical forecast. **Referenced table:** HistoricalDemandCategory	Reference	
AutoRegressive Terms	Specifies the auto-regression terms used in an ARIMA forecast calculation. Values for this field are typically a list of lag numbers. For example, `1,2,4` specifies the ARIMA model considers lags 1, 2, and 4 when calculating the statistical forecast. **Default value**: ' '	String	
BaseQuantity	Overrides the forecast quantities for an item to simulate a runout. This override replaces the quantity used in the statistical forecast. **Default value**: 0	Quantity	

Table 6.110: ForecastItemParameters (Mfg) fields

Field name	Description	Data type	Key
BestFitForecastLag	If using best fit forecasting with a holdout period, this indicates the first interval in the holdout period in which simulated forecasts generated from fitted models are compared against historical actuals for the purpose of calculating forecast error. A value of "1" is used by default and indicates to start the evaluation process in the first interval of the holdout period. Alternatively, a larger value can be specified to offset the forecast evaluation later into the holdout period. Typically, this might be used to account for a factor of lead time. This value should be expressed in intervals of the **SOPAnalyticsConfiguration.CycleCalendar**. **Default value**: 1 **Note:** This field is only applicable to forecast items where the **BestFitHoldoutPeriodIntervalCount** field contains a positive value, and where the **Type** reference has **ForecastModel** set to "BestFit" and **HoldoutPeriodUsageRule** set to either "SimpleHoldout" or "Simulation". For more information, see "Using best fit with a holdout period" on page 2053.	Integer	
BestFitHoldout PeriodInterval Count	Defines the duration of the holdout period used for best fit forecasting (expressed in intervals of the **SOPAnalyticsConfiguration.CycleCalendar**) The holdout period is applied immediately before **RunDate** and indicates the historical periods whose data is held out (excluded) when fitting statistical models to historical data. Instead, this period is used for evaluation purposes as simulated forecasts based on each of the fitted models are compared against the actuals in the holdout period. The model that minimizes the chosen error measure is then used to generate the statistical forecast starting at **RunDate**. **Default value**: 0 **Note:** This field is applicable only to those items whose **Type** reference has **ForecastModel** set to "BestFit" and **HoldoutPeriodUsageRule** set to "SimpleHoldout" or "Simulation". For more information, see "Using best fit with a holdout period" on page 2053.	Integer	

Table 6.110: ForecastItemParameters (Mfg) fields

Field name	Description	Data type	Key
BestFitProfile	A reference to a named profile used in best fit statistical forecasting (applicable when the item's **Type.ForecastModel** reference is "BestFit"). Each profile defines a group of statistical models that are considered during best fit forecasting for the item, along with parameter values applicable to certain models (these parameter values override corresponding parameters on this table). You can use a profile to include only the models which are most applicable to a given item. As a result, it can help reduce processing time by excluding other less appropriate models from the fitting process. Otherwise, if this reference is Null then all supported statistical models (other than optional "Rforecast" model) are considered when best fit forecasting is used for the item, and parameter values are as defined on this table. **Referenced table:** BestFitProfile (Nullable)	Reference	
BestFitProfile Detail	Specifies a specific forecast model and associated parameters to be automatically chosen and applied in best fit forecasting (applicable when the item's **ForecastItemType.Model** is "BestFit"). This field is typically populated after best fit forecasting has been run and the recommended model is deemed appropriate for the item. This locks the selected model to the item, and prevents the selection of a different model if statistical forecasting is run in the future. When this reference is Null, then the best fit forecasting process proceeds as normal through all applicable models. **Referenced table:** BestFitProfileDetail (Nullable)	Reference	
Constant	Indicates whether a constant value, also known as the Y intercept, is included in an ARIMA or ARIMAX forecast calculation. Valid values are: • **Use**—The constant is used in the calculation. • **Ignore**—For ARIMA, The constant is not used in the calculation. For ARIMAX, **Ignore** forces the constant term to be zero. **Default value**: Ignore	String	

Table 6.110: ForecastItemParameters (Mfg) fields

Field name	Description	Data type	Key
ConfidenceLevel	A confidence level used to calculate prediction intervals in statistical forecasts that are generated using one of the following statistical forecasting models: • ARIMA • ARIMAX • Double exponential smoothing • Exponential smoothing • Holt-Winters (multiplicative and additive) • Linear • Multiple Linear Regression • Rforecast • Step-wise ARIMA Values between .5 and 0.9999 should be provided. Any value >= 1 is treated as 0.9999 to determine StatisticalForecast.PredictionIntervalLower and StatisticalForecast.PredictionIntervalUpper. Any value <= 0 indicates to ignore the field. **Note:** The value in this field is always ignored for items where a non-null reference is specified in **ForecastProfile** field, or a positive value is provided in either of the **BaseQuantity**, or **ScalingFactor** fields.	Quantity	
DifferenceLevel	The number of differencing operations to perform when calculating an ARIMA or ARIMAX function. If you enter a negative DifferenceLevel using ARIMA, ARIMA is not used. However, if you enter a negative DifferenceLevel using ARIMAX, the order is automatically chosen. **Default value**: -1 **Note:** It is strongly recommended that you do not enter a value that is greater than 2 in this field.	Integer	

Table 6.110: ForecastItemParameters (Mfg) fields

Field name	Description	Data type	Key
ElasticNetParameter	A parameter, also known as alpha, that can be from 0 to 1 (inclusive) that controls how much penalization of the L1 and L2 norms is applied when using the Elastic Net forecast model. Elastic Net combines both the LASSO and ridge regression techniques to shrink coefficients. The value 1 is equivalent to LASSO and 0 is equivalent to ridge. This parameter works in conjunction with RegularizationParameter. **Default value**: 1 **Note:** This field was added in Version 2016.2, Service Update 27.	Quantity	
ForecastCategory	A reference to the forecast category the statistical forecast is generated for. Each forecast item can have one statistical forecast generated per forecast category. **Referenced table:** HistoricalDemandCategory	Reference	Yes
ForecastInterval Count	The number of future periods to generate the statistical forecast for. This value is expressed in terms of the **Type.IntervalsCalendar** reference.	Integer	
ForecastProfile	The profile points to apply to a statistical forecast. Points defined in the profile are applied starting at the **ProfileStartDate**. **Referenced table**: PointsProfile (Nullable)	Reference	
HistoricalInterval Count	The number of periods of historical demand to use as input into generating the statistical forecast. This value is expressed in terms of the **Type.IntervalsCalendar** reference.	Integer	

Table 6.110: ForecastItemParameters (Mfg) fields

Field name	Description	Data type	Key
HistorySkip LeadingZeros	Determines whether the first period bucket or buckets in the **ForecastItemParametersActual** table generate records in the **StatisticalForecastPredictActual** if the demand in these first period buckets is a quantity of zero (leading zeros). **Y**—Leading zeros are ignored when calculating historical data and the calculation begins with the first occurrence of a non-zero data point. **N**—Leading zeros are not ignored when calculating historical data. **Default value:** N **Note:** If **HistorySkipLeadingZeros** is set to "Y", the statistical forecast is computed beginning with the first bucket in the historical demand period (based on **ForecastItemParameters.HistoricalIntervalCount** and **ForecastItemParameters.HistoricalStartDate**) for which the demand quantity is not zero, but only if all earlier period buckets in the **ForecastItemParametersActual** table have a demand of zero. If the first period buckets in the table have demands with positive quantities, leading zeros are not ignored. **Note:** This field was added in Version 2016.2 Service Update 10.	Boolean	
HistoryStartDate	The first date when actual demand for the forecast item is available for use in calculating the forecast. This is used to set a start date for collecting historical data when there is less data available than the **HistoricalIntervalCount** setting implies. This avoids including empty historical periods in forecast calculations. For example, if there is 9 months of history available for the item, but **HistoricalIntervalCount** is set to "12", then this field could be set to a date 9 months before the **RunDate**.	Date	

Table 6.110: ForecastItemParameters (Mfg) fields

Field name	Description	Data type	Key
IgnoreBestFitProfileDetailParameters	When a forecast item is using a **BestFitProfile** to define the list of models to be considered for BestFit, this parameter ignores the model parameter values that are associated with the profile in **BestFitProfileDetails** and applies the model parameter values from the **ForecastItemParameters** record to the models in the profile instead. The following values are valid: • **Y**—Use the model parameters in the **ForecastItemParameters** record instead of those specified in **BestFitProfileDetails**. • **N**—Use the model parameters in the **BestFitProfileDetails** records. **Default value: N** **Note:** For more information, see "Applying best fit profiles" on page 2056.	Boolean	
Item	A reference to the forecast item this set of parameters applies to. **Referenced table:** ForecastItem	Reference	Yes
MovingAverage IntervalCount	Number of previous periods of demand, expressed in terms of the **Type.IntervalsCalendar** reference, to use for statistical forecasts calculated using the MovingAverage or BestFit models as follows: • If < 0 and **Type.ForecastModel** is set to "BestFit", then "MovingAverage" is excluded from consideration. • If = 0 and **Type.ForecastModel** is set to "BestFit", then this value is calculated for the statistical forecast so as to minimize the error measure set by **Type.FitMeasure**. • If <=0 and **Type.ForecastModel** is set to "MovingAverage", then this value is calculated for the statistical forecast so as to minimize the error measure set by **Type.FitMeasure.** • If > 0 and **Type.ForecastModel** is set to either "MovingAverage" or "BestFit", then the value provided here is used**.** Default value: -1	Integer	

Table 6.110: ForecastItemParameters (Mfg) fields

Field name	Description	Data type	Key
MovingAverage Terms	Specifies the number of moving average terms used in an ARIMA forecast calculation. Values for this field are typically a list of lag numbers. For example, `2,3` specifies that the ARIMA model considers lags 2 and 3 when calculating the statistical forecast. **Default value**: ' '	String	
OutlierMoving AverageWindow	Number of historical intervals used in calculating the moving average for use in outlier detection. Only applicable when **OutlierType.DataRule** is set to "MovingAverageError" which uses the difference between historical data points and the calculated moving average to determine when determining which points are outliers. **Default value:** 3	Integer	
OutlierSmoothing AfterIntervalCount	When smoothing demand outliers for safety stock items, this indicates the default number of **Type.IntervalsCalendar** periods forward over which to spread the values. This occurs after any backward spreading. **Note:** This field was added in Version 2016.2, Service Update 5.	Integer	
OutlierSmoothing BeforeIntervalCount	When smoothing demand outliers for safety stock items, this indicates the default number of **Type.IntervalsCalendar** periods backward over which to spread the values. This occurs after any forward spreading. **Note:** This field was added in Version 2016.2, Service Update 5.	Integer	

Table 6.110: ForecastItemParameters (Mfg) fields

Field name	Description	Data type	Key
OutlierThreshold	Sets a threshold for detecting outliers within historical data used in generating the statistical forecast. The value must be > 0. This value is used to determine both a value above which a point is considered an outlier (upper threshold) and a value below which a point is considered an outlier (lower threshold). The actual interpretation of the value in this field is influenced by the **OutlierType.DetectionRule** setting as follows: • **IglewiczHoaglinMethod**—A modified Z-score. The Z-score value of should be based on the Normal Distribution table. A Z-score of less than 2.33 corresponds to a 99% probability that the data point is not an outlier. The following table lists probabilities and their corresponding Z-score: **% Prob** / **Z-score** 90.0 / 1.28 95.0 / 1.64 96.0 / 1.75 97.0 / 1.88 98.0 / 2.05 99.0 / 2.33 99.5 / 2.58 99.6 / 2.65 99.7 / 2.75 99.8 / 2.88 99.9 / 3.09 • **StandardDeviation**—Number of standard deviations from the mean. For example, 3 indicates that points more than three standard deviations from the mean are considered outlier. • **Winsorizing**—A percentile within the data. A value between .01 and .49 should be specified. For example, .05 indicates that points below the 5th percentile or above the 95th percentile are considered outliers. **Default value:** 3	Quantity	
OutlierType	A reference to a set of processing rules that define how outliers in historical data are identified and subsequently processed. **Referenced table:** OutlierType (Nullable)	Reference	

Table 6.110: ForecastItemParameters (Mfg) fields

Field name	Description	Data type	Key
ProfileStartDate	The date to begin applying the **ForecastProfile**, **BaseQuantity**, and **ScalingFactor** for a statistical forecast.	Date	
RegressionModel	A reference to the regression model that is used by the forecast item. This field applies only to forecast items that are using multiple linear regression to generate the statistical forecast. **Referenced table:** RegressionModel (Nullable) **Note:** This field was added in Version 2016.2, Service Update 27.	Reference	
RegularizationParameter	A parameter, also known as lambda, that controls the strength of the penalty term for coefficients that is used in Elastic Net regression. This parameter is dependent on the ElasticNetParameter to shrink the coefficients of regressors. The value that is used for RegularizationParameter is reported in the StatisticalForecastFitOutput table. **Default value**: -1 **Note:** If you set a negative value in this field, the value of the regularization parameter will be chosen by the model. Because the implementation of the underlying model in R involves randomization, you may notice that the value of the regularization parameter and the statistical forecast that is generated may be different from run to run. **Note:** This field was added in Version 2016.2, Service Update 27.	Quantity	

Table 6.110: ForecastItemParameters (Mfg) fields

Field name	Description	Data type	Key
ResidualAutocorrelationConfidenceLevel	A value used to calculate confidence levels for residual autocorrelation when using statistical forecasts that are generated using one of the following statistical forecasting models: • ARIMAX • Elastic Net • Multiple Linear Regression Autocorrelation measures the relationship between the residuals in one time period to the residuals in a previous, or lagged, time period to determine the correlation between the two values. Values must be between 0 and 1. Values that are <0 or >1 result in upper and lower confidence bounds of -1, which indicates that no confidence interval was generated. **Default value**: .95 **Note:** This field was added in Version 2016.2, Service Update 27.		
Reviewed	Whether the newly-entered forecast item has been reviewed for correctness. This field is for reporting only. **Default value**: N	Boolean	
RollingError IntervalCount	Indicates the number of intervals in the holdout period that should be used for measuring forecast error when the "RollingLagPercentageError" fit measure is chosen. This value is specified in **SOPAnalyticsConfiguration.CycleCalendar** intervals. If the value specified is greater than the number of intervals in the holdout period, then forecast error calculations continue until **RunDate**. This field is only applicable for items whose **Type** reference has **ForecastModel** set to "BestFit" and **HoldoutPeriodUsageRule** set to a value other than "Ignore". **Default value:** 3	Integer	

Table 6.110: ForecastItemParameters (Mfg) fields

Field name	Description	Data type	Key
RParameterSet	A reference to an optional set of parameter values to be used by named forecasting functions in the R statistical programming language. This reference is only applicable when the **ForecastModel** is set to "Rforecast", and is intended for advanced uses. If left Null when using "Rforecast", then the functions in R are run using a standard set of parameters based on field values and data passed from RapidResponse. **Referenced table:** RParameterSet (Nullable) **Note:** This field supports the optional R Forecast capability.	Reference	
ScalingFactor	A multiplier applied to the **BaseQuantity** value for the forecast items. Values less than zero are ignored. **Default value**: 1	Quantity	

Table 6.110: ForecastItemParameters (Mfg) fields

Field name	Description	Data type	Key
SeasonalInterval Count	This field indicates the number of intervals in a season, in terms of the **Type.IntervalsCalendar** reference, for statistical forecasts calculated using the BestFit, Elastic Net, HoltWintersMethod, MultipleLinearRegression, or Rforecast models as follows: • If < 0 and **Type.ForecastModel** is set to BestFit, then HoltWintersMethod and MultipleLinearRegression are excluded from consideration. Therefore, it does not try to find seasonality. • If < 0 and **Type.ForecastModel** is set to Rforecast, then this value is calculated as 1 and no seasonality is applied. • If < 0 and **Type.ForecastModel** is set to Elastic Net or MultipleLinearRegression, then no seasonality is applied. • If = 0 and **Type.ForecastModel** is set to BestFit, then this value is calculated for the statistical forecast so as to minimize the error measure set by **Type.FitMeasure**. • If = 0 and **Type.ForecastModel** is set to Rforecast, Elastic Net, or MultipleLinearRegression, then R chooses the seasonality value that is calculated for the statistical forecast. • If <= 0 and **Type.ForecastModel** is set to HoltWintersMethod, then this value is calculated for the statistical forecast so as to minimize the error measure set by **Type.FitMeasure**. • If > 0 and **Type.ForecastModel** is set to either BestFit, Elastic Net, HoltWintersMethod, MultipleLinearRegression, or Rforecast, then the value provided here is used. Default value: -1 **Note:** The support for the Rforecast was added in Version 2016.2 Service Update 13. The support for the MultipleLinearRegression was added in Version 2016.2 Service Update 27.	Integer	
StartDate	The first date the forecast for this item is calculated. Values earlier than this date are considered to be zero. If this value is Undefined, Past is used.	Date	

Table 6.110: ForecastItemParameters (Mfg) fields

Field name	Description	Data type	Key
StopDate	The last date the forecast for this item is calculated. Values later than this date are considered zero. If this value is Undefined, Future is used.	Date	
TrendDecayFactor	A decay factor to dampen trend that can be applied to the following forecast models: • AdditiveHoltWintersMethod • DoubleExponentialSmoothing • ElasticNet • HoltWintersMethod • MultipleLinearRegression • Rforecast For AdditiveHoltWintersMethod, DoubleExponentialSmoothing, and HoltWintersMethod, if the trend should decay over time, this value must fall between 0 and 1. All values less than 0 result in complete elimination of the trend. If neither decay nor elimination is required, this value should be 1 or greater. For ElasticNet and MultipleLinearRegression, the trend damping applies only to the generated statistical forecast, not to past fitted values. In addition, if you enter a TrendDecayFactor that is equal or less than 0, this will result in complete elimination of the trend. If neither decay nor elimination is required, this value should be 1 or greater. For Rforecast, if you enter a TrendDecayFactor that is less than 0 or equal or greater than 1, then trend is dampening is ignored. If you enter a value of 0, then R automatically detects trend and the forecast model can select decay factor as part of the fit. If TrendDecayFactor is greater than 0 and less than 1, then this value is used for trend dampening. The use of the decay factor is controlled by the **TrendDecayFactorRule** option on the **ForecastItemParametersType** table.	Quantity	
Type	A value that determines processing policies for this set of forecast item parameters such as the forecast model and planning calendar to use when generating the statistical forecast. **Referenced table:** ForecastItemParametersType	Reference	

Table 6.110: ForecastItemParameters (Mfg) fields

Field name	Description	Data type	Key
UnitofMeasure	The unit of measure that is used in the statistical forecast generated for this record. All inputs used in the statistical forecast are converted to this unit of measure. **Referenced table:** UnitOfMeasure table **Note:** To successfully use the **Unit of Measure** control in any of the workbooks, it's necessary to assign a forecast item unit of measure to forecast items even if they are reported in the same unit of measure as their part-customers. **Note:** This field was added in Version 2016.2 Service Update 12.	Reference	
UseOwnDemand	Whether historical demand for this forecast item is included in determining the total historical demand that is used to calculate the item's statistical forecast. The following values are valid: • **Use**—The demand for this forecast item is included in determining the total historical demand. • **Ignore**—The demand for this forecast item is not included in determining the total historical demand.	String	
WeightsDecayFactor	The factor to use to decrease the influence of regressors over time. When WeightDecayFactor is set, the regressor values in more recent time periods are given more importance than the values in earlier time periods in the statistical forecast calculation. It is an optional value that is used to improve model fit. You can apply WeightsDecayFactor to a forecast item that uses the Elastic Net or Multiple Linear Regression statistical forecasting methods. This value must fall be greater than 0 and less than 1. You cannot use a negative value. The formula used to calculate weight decay is as follows: For the t-th observation in the historical set Quantity = WeightsDecayFactor^ (HistoricalIntervalCount - t) **Default value**: 1 **Note:** This field was added in Version 2016.2, Service Update 27.	Quantity	

ForecastItemParameters table – calculated and set fields

The following describes the calculated and set fields in the **ForecastItemParameters** table. For an introduction to this table, and descriptions of its input fields, see "ForecastItemParameters table" on page 296.

Table 6.111: Calculated ForecastItemParameters (Mfg) fields

Field name	Description	Data type	Key
CalcBestFitProfile Detail	If a profile was used in best fit forecasting for the item, this returns a reference to the actual **BestFitProfileDetail** record associated with the chosen forecast model and parameters. Otherwise, this reference is Null.	Reference	
Disaggregation Rates	Set of statistical forecast disaggregation rates calculated for the forecast item.	Set	
EffectiveForecast Model	The model used to generate the statistical forecast associated with this item. For all forecast models other than "BestFit", this always returns the referenced **ForecastModel** value from the **ForecastItemParametersType** table. For the "BestFit" forecast model, this returns one of the following: • The **ForecastModel** referenced from the **ForecastItemParametersType** table (if the **BestFitProfileDetail** reference is Null). • The **ForecastModel** referenced from the **BestFitProfileDetail** table (if the **BestFitProfileDetail** reference is populated).	String (Enum)	
EffectiveHistory StartDate	The earliest **HistoryStartDate** value for this forecast item or any other item referenced from the **ForecastItemParametersMap** table. Any Undefined dates are ignored. If all dates are Undefined, Past is returned.	Date	
EventStatistical ForecastDetails	Set of statistical forecast quantities for events for the forecast item.	Set	
FitOutput	Set of forecast item outputs associated with this ForecastItemParameters record.	Set	
ForecastItem ParametersActuals	Set of historical demands for the forecast item.	Set	

Table 6.111: Calculated ForecastItemParameters (Mfg) fields

Field name	Description	Data type	Key
ForecastItem Parameters FitOutputs	Set of forecast item parameters fit outputs associated with this **ForecastItemParameters** record.	Set	
ForecastItem ParametersMaps	Set of mappings defined for this ForecastItemParameters record.	Set	
ForecastItemParameters OutlierCalcs	Set of outlier calculations used for a forecast item.	Set	
ForecastItemParameters OutlierFitOutputCalcs	Set of outlier fit output calculations used for a forecast item.	Set	
ForecastItem Parameters ReferenceMaps	Set of referenced mappings defined for the ForecastItemParameters record.	Set	
ForecastItemParameters RegressionWeights	Set of regression weights used for the forecast item.	Set	
ForecastItemParameters Regressors	Set of regressors associated with this forecast item.	Set	
ImportedStatistical Forecasts	Set of imported statistical forecast records for the forecast item. **Note:** This field was added in Version 2016.2, Service Update 5.	VectorSet	
Outliers	Set of outlier adjustments for the forecast item.	Set	
RegressionCoefficients	Set of regression coefficients generated for a forecast item.	Set	
StatisticalForecasts	Set of statistical forecasts calculated for the forecast item.	Set	
StatisticalForecast Details	Set of disaggregated statistical forecast quantities for the forecast item.	Set	
StatisticalForecast FitOutputs	Set of statistical forecast item outputs associated with this **ForecastItemParameters** record.	Set	
StatisticalForecast PredictActuals	Set of forecast parameters generated for the forecast item that have been fitted with historical actuals.	Set	

ForecastItemParametersFitOutput table

The **ForecastItemParametersFitOutput** table saves the fit output generated by **StatisticalForecastFitOutput**, a calculated table. The fit output consists of statistical model parameters used to calculate the statistical forecast and various calculated data characteristics and error measures of the statistical model.

This table is used in RapidResponse 2014.4 (or later) by running the **Generate and Save Forecast** command in the **S&OP Forecast Item Management** workbook and when **ForecastItemParametersType.ModelConstantUsage** is set to "Use". The model constants used in the statistical forecast calculations are provided by this table.

Table 6.112: ForecastItemParametersFitOutput (Mfg) fields

Field name	Description	Data type	Key
BestFitProfile Detail	A reference to the detailed profile, and associated parameters, used in the process of fitting and selecting the best forecast model. This reference is populated on records where **Class** is "BestFit", and a best fit profile was used in selecting the model. **Referenced table:** BestFitProfileDetail	Reference	
Class	The type or category of forecast parameter being reported in the record. The name of the parameter is reported in the **ValueName** field for all classes except Message. Valid values are: • **BestFit**—the statistical model with the least margin of error. This field reports "BestFit" when **ForecastItemParametersType.ForecastModel** is set to "BestFit". The three models with the least margin of error are reported in the **ValueName** field. • **DataCharacteristic**—a characteristic of the input data points. • **ErrorMeasure**—an error measure of fitted values against the input data points. • **Message**—a message type generated from the statistical models. The message is available in the **ValueText** field. • **ModelConstant**—the constant values used by the forecast model. • **ModelOutput**—the output from the statistical model that will be used to generate forecast. • **StepWiseARIMA**—the ARIMA model with the least margin of error. This field reports "StepWiseARIMA" when **ForecastItemParametersType.ForecastModel** is set to "StepWiseARIMA". The three models with the least margin of error are reported in the **ValueName** field.	String (Enum)	

Table 6.112: ForecastItemParametersFitOutput (Mfg) fields

Field name	Description	Data type	Key
ForecastModel	The statistical model that will be used to calculate the statistical forecast. For more detailed information about the forecast models supported by RapidResponse, see "Statistical forecasting models" on page 2031. Valid values are: • **AdditiveHoltWintersMethod**—differs from the Holt-Winters model in that forecast points are calculated in an additive, rather than multiplicative, manner. Suitable for demand that has constant variation over a period. For a more detailed description, see "Holt-Winters multiplicative and additive" on page 2037. • **ARIMA**—calculates forecasts for a time period using a linear combination of actual values and error values in a time series. This model can be used on a stationary time series, or a differencing function can be applied to non-stationary data to make it stationary. For a more detailed description, see "Auto-Regressive Integrated Moving Average (ARIMA)" on page 2034. • **ARIMAX**—Is an extension of the ARIMA model, but also includes independent variables (regressors) in the forecast calculation. This makes ARIMAX a multiple linear regression model. To improve forecast accuracy, ARIMAX also takes into consideration autocorrelation that may be found in regressor residuals. For a more detailed description, see "ARIMAX" on page 2042. • **BestFit**—fits each of the other forecast models and selects the one with the least margin of error. For a more detailed description, see "Best fit" on page 2053. • **CrostonsMethod**—uses exponential smoothing with a single smoothing constant for the forecast values, but calculates two different values; the first being the forecast values at a point, and the second being the average length of time between forecasts. These values determine the forecast quantities and the periods that have forecast demands. Suitable for demand that is not constant, such as lumpy demand that contains periods of zero quantities. For a more detailed description, see "Croston's method" on page 2034. • **DoubleExponentialSmoothing**—considers the data points and trends within the historical data, and applies a smoothing algorithm to both. The result is then used as the statistical forecast. Suitable for demand that is fairly stable but trending up or down over time. For a more detailed description, see "Double exponential smoothing" on page 2036. • **ElasticNet**—A multiple linear regression model that uses regularized, also known as penalized, regression methods. It blends Lasso and ridge regression techniques by penalizing both L1 and L2 norms to reduce the coefficient vector. To use ElasticNet, you must attach a minimum of two	String (Enum)	

Table 6.112: ForecastItemParametersFitOutput (Mfg) fields

Field name	Description	Data type	Key
	regressors to a forecast item or you won't be able to generate a statistical forecast. For a more detailed description, see "ElasticNet" on page 2043. • **ExponentialSmoothing**— considers data points within the historical data, and applies a smoothing algorithm. The result of the final data point is then used as a constant value for the statistical forecast. Suitable for demand that is fairly stable and lacks a trend. For a more detailed description, see "Exponential smoothing" on page 2037. • **ForecastImport**—means that the statistical forecast is generated using an external tool. The statistical forecast values that are generated using an external tool are saved in the ImportedStatisticalForecast table. For more information, see "ForecastImport" on page 2058. • **HoltWintersMethod**—similar to double exponential smoothing in that it considers data points and trends within the historical data, but also accounts for seasonal trends. That is, the values for each point in the forecast and trend are further adjusted to account for seasonal demand changes. This model is the Holt-Winters multiplicative method, so it is suitable for demand that has proportional variation over a period. For a more detailed description, see "Holt-Winters multiplicative and additive" on page 2037. • **Linear**—performs a linear regression on a set of historical data points to generate a trend line that determines statistical forecast quantities. Suitable for demand that does not fluctuate. For a more detailed description, see "Linear" on page 2039. • **MovingAverage**—calculates the simple moving average of a specified number of previous data points to generate a constant forecast. Suitable for demand that is fairly stable and does not change much over time. For a more detailed description, see "Moving average" on page 2039. • **MultipleLinearRegression**—Performs a linear regression using multiple independent variables to predict the outcome of one dependent variable. For a more detailed description, see "Multiple linear regression" on page 2043. • **StepWiseARIMA**—identical to the ARIMA model, but all parameters are calculated automatically. Step-wise ARIMA selects the order of difference through KPSS unit-root tests and selects AR order and MA order by minimizing AIC. For a more detailed description, see "Step-wise ARIMA" on page 2039. **Note:** This field was modified in Version 2016.2, Service Update 27.		

Table 6.112: ForecastItemParametersFitOutput (Mfg) fields

Field name	Description	Data type	Key
ItemParameters	A reference to the input parameters used in generating the statistical forecast for a given forecast item. **Referenced table:** ForecastItemParameters (Owner)	Reference	Yes
ValueDate	The forecast parameter **MeanDate**, a data characteristic, is expressed as a date. This field is populated if the value in the **ValueType** field is "Date".	Date	

Table 6.112: ForecastItemParametersFitOutput (Mfg) fields

Field name	Description	Data type	Key
ValueName	The name of the forecast parameter. The **Class** field provides the category of the forecast parameter, then the **Name** field provides the specific parameter being reported, so various names could be reported for a given class. For example, if "ModelConstant" is the class of the parameter, the name could be "Alpha", indicating that the forecast model uses the alpha constant when performing its calculations (alpha's quantity is then reported in the **ValueQuantity** field). Data characteristics: • **Count**—reports the number of values in your input set. • **MeanDate**—determines the average of all dates included in the statistical forecast, and the approximate midpoint of the dates used in the statistical calculations. • **MeanQuantity**—determines the average of all actual values in the input data. • **StandardErrorOfY**—determines how values differ from the mean. • **TotalSumSquares**—determines the total difference between each data point and the mean. • **Variance**—determines how data values differ from the mean. For more information about data characteristics, see "Statistical forecasting models" on page 2031. Error measures: • **AdjustedRSquared**—determines the ratio between the regression sum of squares and total sum of squares measures, but is influenced by the number of values in the input data set. • **AkaikeInformationCriterion (AIC)**—determines how well a statistical model fits the values it was generated from using the log-likelihood result and double the number of estimated parameters. This measure is reported only if the ARIMA or Step-wise ARIMA models are used. • **ForecastError**—determines forecast accuracy by showing the adjusted error of the predicted actuals compared to the historical actuals. • **Hannan-QuinnCriterion (HQC)**—determines how well a statistical model fits the values it was generated from, using the log-likelihood result and the product of double the number of parameters and the logarithm of the logarithm of the number of observed samples. This measure is reported only if the ARIMA or Step-wise ARIMA models are used. • **LogLikelihood**—determines the maximum likelihood for a statistical function. This measure is reported only if the ARIMA or Step-wise ARIMA models are used. • **MeanAbsoluteError**—determines the absolute value of the variance between the historical actual values and the	String (Enum)	

Table 6.112: ForecastItemParametersFitOutput (Mfg) fields

Field name	Description	Data type	Key
	predicted forecast values. • **MeanAbsoluteErrorByMean**—normalizes the value returned by the mean absolute error measure by dividing it by the mean quantity of the input data. • **MeanAbsolutePercentageError**—determines the absolute value of the variance between the historical actual values and the predicted forecast values with respect to the actual values, expressed as a percentage. • **MeanAbsolutePercentageErrorByForecast**—determines the absolute value of the variance between the historical actual values and the predicted forecast values with respect to the forecast values, expressed as a percentage. • **MeanAbsoluteScaledError (seasonal)**—determines the mean absolute error of the forecast divided by the mean absolute error of the seasonal naïve forecast. • **MeanError**—determines the average variance between the historical actual values and the predicted forecast values. • **MeanPercentageError**—determines the average variance between the historical actual values and the predicted forecast values with respect to the actual values, expressed as a percentage. • **MeanPercentageErrorByForecast**—determines the average variance between the historical actual values and the predicted forecast values with respect to the forecast values, expressed as a percentage. • **MeanSquareErrors**—calculates the average of the residual sum of squares for the forecast. • **RegressionSumSquares**—determines the difference between the total sum of squares of the input data and the residual sum of squares, and shows how the variance of the statistical forecast and input values differs from the variance of the input values and average of input values. • **ResidualSumSquares**—calculates the sum of the square of differences between the historical actual values and the values predicted by the statistical forecast. • **RootMeanSquareErrors**—determines the square root of the value produced by the mean square errors measure, and shows the correlation between the historical actual values and the results of the statistical forecast calculation. • **RSquared**—determines the ratio between the regression sum of squares and total sum of squares measures, and shows how closely the forecast values fit the historical actual values. • **SchwarzBayesianInformationCriterion (SBC)**—determines how well a statistical model fits the values it was generated from using the log-likelihood result and the product of the number of parameters and logarithm of the number of observed samples. This measure is reported only if the		

Table 6.112: ForecastItemParametersFitOutput (Mfg) fields

Field name	Description	Data type	Key
	ARIMA or Step-wise ARIMA models are used. • **VarianceError**—determines if the forecast model produces forecasts with more stable forecast errors or unstable, varying forecast errors by showing how widely the errors are spread around the mean error. For more information about error measures, see "Error measures" on page 2060. Model constants: • **Alpha**—a smoothing constant, required for exponential smoothing, double exponential smoothing, Holt-Winters, additive Holt-Winters, and Croston's method. • **Beta**—a seasonal trend smoothing constant, required for Holt-Winters and additive Holt-Winters. • **Gamma**—a trend smoothing constant, required for double exponential smoothing, Holt-Winters, and additive Holt-Winters. • **Mu**—used only for ARIMA, if a constant is included in the calculation. • **Phi**—used only for ARIMA, and must be provided for each auto-regressive and moving average lag included in the ARIMA calculation. • **Theta**—used only for ARIMA, and must be provided for each auto-regressive and moving average lag included in the ARIMA calculation. Model outputs: • **AutoRegressiveTerms**—the auto-regressive values considered for the ARIMA calculation. • **DifferenceLevel**—determines how many differencing functions are performed on the data when using the ARIMA or ARIMAX model. • **FitError**—any error encountered during the model fit process. Can be either "None", "Error", or "CriticalError". The error message is displayed in the **ValueText** field with "Message" in the **Class** field. • **Forecast**—the calculated forecast quantity reported across all forecast points when using exponential smoothing, moving average, or Croston's method. • **IncludeConstant**—determines whether a constant value is included in the ARIMA and ARIMAX calculations. • **InterarrivalValue**—the final estimated inter-arrival time between forecasts, which is the unrounded SporadicInterval, when using the Croston's method. • **KPSS_UnitRootTest_(i)**—the calculated difference level used in the Step-wise ARIMA calculation. • **MovingAverageIntervalCount**— the specified number of historical periods used to calculate the moving average. • **MovingAverageTerms**—the moving average values		

Table 6.112: ForecastItemParametersFitOutput (Mfg) fields

Field name	Description	Data type	Key
	considered for the ARIMA calculation. • **RegularizationParameter**—A parameter, also known as lambda, that controls the strength of the penalty term for coefficients that is used in Elastic Net regression. • **Root_AR_(i)**—the (i) root of the auto-regressive terms of the ARIMA calculation. • **Root_AR_(i)_Modulus**—the modulus of (i) root of the auto-regressive terms of the ARIMA calculation. • **Root_MA_(i)**—the (i) root of the moving average terms of the ARIMA calculation. • **Root_MA_(i)_Modulus**—the modulus of (i) root of the moving average terms of the ARIMA calculation. • **SeasonalIntervalCount**—the duration of a season, based on the intervals calendar; used for Holt-Winters and additive Holt-Winters. • **SeasonalIntervalCount**—the duration of a season, based on the intervals calendar; used for Elastic Net, Holt-Winters, additive Holt-Winters, and Multiple Linear Regression. • **SeasonalityValue_(i)**—the value calculated for each season; use for Holt-Winters and additive Holt-Winters. • **SmoothedValue**—the value required for statistical models that use smoothing, namely exponential smoothing, double exponential smoothing, Holt-Winters and additive Holt-Winters. For the Croston's method, it is the estimated non-zero demand at every InterarrivalValue. • **TrendValue**—the value used to represent a trend, used for double exponential smoothing, Holt-Winters, and additive Holt-Winters. Best fit: • **ErrorMeasure**—the error measure used to determine the best fit. • The names of the three statistical models with the least margin of error. Step-Wise ARIMA: • The names of the three ARIMA models with the least margin of error. **Note:** The **MeanAbsoluteScaledError** (seasonal) option was added in Version 2016.2, Service Update 13. **Note:** The **Interarrival** model output was added and the **SmoothedValue** was modified in Version 2016.2, Service Update 15. **Note:** The **RegularizationParameter** model output was added in Version 2016.2, Service Update 27. **DifferenceLevel**, **IncludeConstant**, and **SeasonalIntervalCount** were also modified in this update to support multiple linear regression models.		

Table 6.112: ForecastItemParametersFitOutput (Mfg) fields

Field name	Description	Data type	Key
ValueQuantity	Error measures, model constants, model outputs, and most data characteristics are expressed as quantities. This field is populated if the value in the **ValueType** field is "Quantity".	Quantity	
ValueText	Messages or arrays needed for ARIMA are expressed as strings. This field is populated if the value in the **ValueType** field is "String".	String	
ValueType	The data type of the forecast parameter. The data types are: • Text • Quantity • Date	String (Enum)	

ForecastItemParametersMap table

This table defines mappings between forecast items, which allows the historical demand from one item to be used in calculating the statistical forecast of another. For example, for introducing a new product, the history from the item it replaces can be used to calculate the statistical forecast by defining a mapping from the new item to the old.

Table 6.113: ForecastItemParametersMap (Mfg) fields

Field name	Description	Data type	Key
Item	The forecast item parameters the mapping is defined for. **Referenced table**: ForecastItemParameters	Reference	Yes
Multiplier	Scales the historical quantities for the referenced forecast item. **Default value**: 1.0	Quantity	
Lag	The number of **ForecastItemParametersType.IntervalsCalendar** periods after the **HistoryStartDate** at which to begin using the historical demand of the referenced forecast item in statistical forecast calculations. If a negative value is set for Lag, the statistical forecast could begin using the historical demand before the **HistoryStartDate**. **Default value**: 0 **Note:** This field was added in Version 2016.2, Service Update 13.	Integer	
ReferenceItem	The forecast item parameters that are mapped to the **Item**. **Referenced table**: ForecastItemParameters	Reference	Yes

ForecastItemParametersOutlier table

The **ForecastItemParametersOutlier** table is an input table. It stores outlier adjustments at the forecast item level, which means that items that belong to more than one forecast category in **ForecastItemParameters** can use different outlier adjustments for each category.

Table 6.114: ForecastItemParametersOutlier

Field name	Description	Data type	Key
Date	The date of the outlier.	Date	
ForecastItem Parameters	A reference to the forecast item the outlier adjustments should be applied to. **Referenced table:** ForecastItemParameters	Reference	Yes
Id	A unique string identifier for the outlier adjustment.	String	Yes
Notes	Descriptive notes appended to this record This field can used to enter notes about a ForecastItemParametersOutlier. Each time a note value is added to this field through a worksheet, a new record is automatically created in the ForecastItemParametersOutlier_Notes table with a date and timestamp, user ID, note text, and a reference to the ForecastItemParametersOutlier record against which it was created. **Referenced table:** ForecastItemParametersOutlier_Notes	Reference	
ProcessingRule	Specifies when the outlier adjustment defined on this record should be used. Valid values are: • **All**—the quantity on the record is used in both statistical forecasting and the outlier detection process. • **StatisticalForecastOnly**—the quantity on the record is used in statistical forecasting only (ignored during the outlier detection process).	String (Enum)	
Quantity	The quantity of the outlier adjustment. This can be a negative value.	Quantity	

ForecastItemParametersRegressionCoefficient table

This table saves the regression coefficients that are generated by **StatisticalForecastRegressionCoefficient**, which is a calculated table. The coefficients help determine if the regressors play a significant role in predicting demand. The table saves the coefficients the first time you generate a statistical forecast for a forecast item that uses a multiple regression model, such as

ARIMAX or Elastic Net. Once the coefficients are saved to this table, they are used in all subsequent forecasts, instead of being recalculated. However, to save coefficients to and to use the coefficients from the **ForecastItemParametersRegressionCoefficient** table, **ForecastItemParametersType.ModelConstantUsage** must be set to **Use**. For more information, see "ForecastItemParametersType table" on page 727

The reporting of the coefficient results also reflect the following:

- Values in the **ForecastItemParameters.WeightsDecayFactor**.
- Values in the **ForecastItemParameters.RegularizationParameter**.
- Values in the **ForecastItemParameters.ElasticNetParameter**.
- Trend and seasonality as reported by R.

Notes:

- Depending on the forecast model that you choose, not all properties of the regression coefficients are reported. For example, if you are using the Elastic Net model, only the **Estimate** is reported. If you are using ARIMAX, only **Estimate** and **StandardErrors** are reported.
- The **Estimate** field is the only field in this table that is used in calculations that are reported in the **StatisticalForecast** forecast table.

The **ForecastItemParametersRegressionCoefficient** table supports the Demand Planning and Statistical Forecasting application in RapidResponse. This table is populated by running the **Generate and Save Forecast** command in the **S&OP Forecast Item Configuration** workbook. The values in this table are reported in the **S&OP Regressor Management** workbook. This table was introduced in version 2016.2 Service Update 27.

Table 6.115: ForecastItemParametersRegressionCoefficient (Mfg) fields

Field name	Description	Data type	Key
Estimate	A value that indicates the direction and magnitude of the relationship between the regressors and demand. It represents the mean change in the regressors' response given one unit change in the demand. • A positive estimate indicates that an increase of the regressors results in an increase in demand. • A negative estimate indicates that an increase of the regressors results in a decrease in demand.	Quantity	
ItemParameters	A reference to the forecast item that is associated with these regression coefficients. **Referenced table**: ForecastItemParameters	Reference	Yes
Name	The unique name that is used to identify the model term, or intercept, that is associated with these coefficients.	String	Yes

Table 6.115: ForecastItemParametersRegressionCoefficient (Mfg) fields

Field name	Description	Data type	Key
pValue	A value that indicates the statistical significance of the correlation between demand and the regressor. It reflects the probability that the observed relationship between demand and the regressors in the historical data would hold true were they not correlated. • A low p-value indicates that there is a correlation between the regressors and demand. • A high p-value indicates that there is little correlation between the regressors and demand.	Quantity	
StandardError	A value that represents the standard deviation of the statistical sample mean. By analyzing the spread of the data points in the historical data, the standard error measures how closely the historical data represents the overall data set. The more data points are measured in the calculation of the mean results in a lower standard error. A lower standard error indicates the more representative the sample is of the overall data set. This value is always positive.	Quantity	
tStatistic	A value that represents the estimate divided by the standard error. You can use the tStatistic to determine if you should support or reject that the regression coefficient is equal to 0 (null hypothesis). A high t-statistic indicates a greater statistical significance, therefore, provides evidence that the regression coefficient is not equal to 0.	Quantity	

HistoricalCurrencyConversion table

This table contains historical conversion rates for currencies. The conversion rates from the **CurrencyConversionForecast** table can be periodically written to this table to maintain historical records of rates.

Table 6.116: HistoricalCurrencyConversion (Core) fields

Field name	Description	Data type	Key
Currency	The currency the rate is calculated for. **Referenced table**: Currency	Reference	
Date	The date the historical conversion was calculated on.	Date	
Header	The historical conversion header associated with a historical conversion. **Referenced table**: HistoricalCurrencyHeader	Reference	
Rate	The historical conversion rate.	Quantity	

HistoricalCurrencyHeader table

This table identifies historical currency conversion rate series, which can be used to report currency conversion rates from previous periods.

Table 6.117: HistoricalCurrencyHeader (Core) fields

Field name	Description	Data type	Key
AsOfDate	The date the historical rate series was created.	Date	
BaseKey	A String representation of the AsOfDate.	String	Yes

HistoricalDemandActual table

This table contains demand data related to historical actual customer shipments on a given date. It might also contain other types of historical actual demand data including consumption of inventory by a customer or point of sale data from a customer.

This table supports Demand Planning and Statistical Forecasting in RapidResponse, and is needed for statistical forecasting, forecast, disaggregation, and forecast accuracy. This table should be integrated during the initial RapidResponse deployment.

This table contains vector set data for records in the **HistoricalDemandHeader** table. For more information about vectors, see "Vector data" on page 138.

If you have upgraded from RapidResponse 2014.2 (or earlier) to RapidResponse 2014.4 (or later) and your company has not converted the five standard tables to contain vector data, the following differences exist in this table:

- The Date field is not a key field.
- The Header field is a reference, not an owning reference.

You can determine whether this table is using vector data by opening the Data Model dialog box and reviewing table icons. Tables that contain vector data are displayed with the icon.

Table 6.118: HistoricalDemandActual (Mfg) fields

Field name	Description	Data type	Key
ActualReceiptDate	The date on which the customer actually received this historical order. **Note:** This field is in the Solutions namespace.	Date	
ActualShipDate	The date on which this historical order was actually shipped to the customer. **Note:** This field is in the Solutions namespace.	Date	

Table 6.118: HistoricalDemandActual (Mfg) fields

Field name	Description	Data type	Key
AutoCommit HorizonDate	The date from which the Order Fulfillment application would have been able to automatically commit to this historical order. That is, if the historical line item's **RequestDate** had been on or after this date, then a commitment would have been automatically made to the customer request (regardless of supply availability). Otherwise, manual intervention would have been needed in order to commit to the customer request. **Note:** This field is in the Solutions namespace.	Date	
CommitDate	The date the order is committed to ship.	Date	
Customer Changes	This field is used to hold a concatenated string of all **CustomerNotes** values that were added to the **IndependentDemandSolution** record to track customer-initiated changes made against this historical demand. **Note:** This field is in the Solutions namespace.	String	
Customer RequestDate	The date on which the customer originally requested to receive this historical order. **Note:** This field is in the Solutions namespace.	Date	
Date	The date associated with this historical demand. This is the date on which the record would be considered for use in statistical forecasting, forecast disaggregation, and/or inventory optimization analytic calculations. For records associated with categories used in statistical forecasting, this field should be set to the request date. For records belonging to categories not used in statistical forecasting, this date should be set to either the request date or the actual shipment date as appropriate.	Date	Yes
DeliveryRoute	A reference to the delivery route that was used to transport this order to the customer. Related details about the delivery such as pick and pack time, transit time, and the carrier that was used are available from this reference. **Referenced table:** DeliveryRoute (Nullable) **Note:** This field s in the Solutions namespace.	Reference	

Table 6.118: HistoricalDemandActual (Mfg) fields

Field name	Description	Data type	Key
DwellTime	Dwell time for this historical order. This represents extra time, if any, that was built into the customer request and during which no activity took place against the order. Calculated as the number of Everyday intervals between **IndependentDemand.RequestDate** and **AutoCommitHorizonDate** at the time the order was first processed in RapidResponse (and not recalculated if the request date subsequently changed).	Integer	
FrozenHorizon Date	The date before which the Order Fulfillment application would not have been able to automatically commit to the customer request date on this historical customer order. That is, if the order's RequestDate had been or before this date, then the commitment would have been pushed outside of the horizon, and manual intervention required to pull it back in and commit to the customer request date. **Note:** This field is in the Solutions namespace.	Date	
Header	A reference to the historical demand header associated with the record. This identifies the part, customer, and demand category for this actual shipment. **Referenced table**: HistoricalDemandHeader **Reference Syntax**: Header.PartCustomer.Part.Name, Header.PartCustomer.Part.Site, Header.Category	Reference (Owning)	Yes
Line	The order line number associated with this record. This field is in the **Solutions** namespace.	String	
LineCreatedDate	When the line number associated with this record was created. This field is in the **Solutions** namespace. **Note:** This field was added in Version 2014.2.	Date	
LineQuantity	The quantity associated with this record. This field is in the **Solutions** namespace.	Quantity	
NumberOf Customer Changes	The number of customer-initiated changes that were made to this historical order during the order fulfillment process. **Note:** This field is in the Solutions namespace.	Integer	
NumberOf SupplyChanges	The number of supply changes that were made to this historical order during the order fulfillment process. **Note:** This field was is in the Solutions namespace.	Integer	

Table 6.118: HistoricalDemandActual (Mfg) fields

Field name	Description	Data type	Key
Order	A reference to the historical demand order number associated with this record. This field is in the **Solutions** namespace. **Referenced table:** Solutions::HistoricalDemandOrder (Nullable)	Reference	
OrderCreation	The date and time at which the historical line item represented by this record was created within the Order Fulfillment application. **Note:** This field is in the Solutions namespace.	DateTime	
OrderPromised DateTime	The date and time at which the Order Fulfillment application was able to promise the historical order to the customer. **Note:** This field is in the Solutions namespace.	DateTime	
Quantity	The number of parts in this actual shipment.	Quantity	
RequestDate	The date by which this order needed to be completed to stock in order to ensure that the order could subsequently ship in time to meet the customer's requested date.	Date	
Route	The routing associated with this record. This field is in the **Solutions** namespace.	String	
ShipSet	The ship set associated with this record. This field is in the **Solutions** namespace.	String	
SupplyNotes	This field is used to hold a concatenated string of all **SupplyNotes** values that were added to the **IndependentDemandSolution** record to track supply-related changes made against this historical demand. **Note:** This field is in the Solutions namespace.	String	
UnitCost	The unit cost for the historical demand. This value can be used in calculating margins where the margin per unit is calculated as the difference between UnitPrice and UnitCost.	Money	
UnitPrice	The unit price for the historical demand. This value can be used to calculate revenue associated with historical actual demand. The default value for **HistoricalDemandActual.UnitPrice** is 0.	Money	

HistoricalDemandCategory table

This table is used to categorize values in both the HistoricalDemandActual and HistoricalDemandSeries tables. It identifies both different categories of forecasted demand (for example, customer, sales, statistical, and so on) as well as different categories of actual demand (for example, shipments, consumption, point of sale, and so on).

If there is no effective record for a given forecast category and part customer combination in of the **HistoricalDemandHeaderTimePhasedAttributes**, **HistoricalDemandHeaderRollingWeight**, **HistoricalDemandCategoryRollingWeight**, or **HistoricalDemandHeader** tables, then the category weight for the part customer is taken from this table.

This table supports Sales and Operations Planning, Demand Planning, and Statistical Forecasting in RapidResponse, and is configured during the initial RapidResponse deployment. Additional values might be entered in this table to support new streams of forecast data.

Table 6.119: HistoricalDemandCategory (Mfg) fields

Field name	Description	Data type	Key
Consensus Forecast Weight	Used to specify a weight to apply to a given forecast category when generating the consensus forecast (as reported in the **ConsensusForecast** table and used to drive supply planning in RapidResponse). This field is applicable only if **Type.ProcessingRule** is set to "Forecast", and typically contains values between 0 and 1. When generating the consensus forecast for a given part and customer combination, the **ForecastDetail.Quantity** value associated with each forecast category on a given date is multiplied by the value in this field, and the results are summed together. As such, only categories where this field is greater than zero are included in the consensus forecast calculation. For example, if the Statistical and Adjustment forecast categories both had this field set to 1, and all other categories were set to 0, the consensus forecast would be the sum of the Statistical and Adjustment categories. If forecast weights by part customer are required, the ConsensusForecastWeight field on the **HistoricalDemandHeader** table can be used to override this value, and if time-phased forecast weights by part customer are required, the ConsensusForecastWeight field on the **HistoricalDemandHeaderTimePhased Attributes** table can be used to override both of these values. Default value: 0 For more information about how the consensus forecast is calculated, see "ConsensusForecast table" on page 966.	Quantity	
CriticalLimit	Indicates the critical level for metric values in this historical demand category expressed as a percentage of their target values. The interpretation of the value provided here depends on the setting in the **DesiredResults** field. If set to "Higher", then the critical limit is reached when below target by the percentage specified here. But if set to "Lower", then the critical limit is reached when above target by the percentage specified here For example, if a value of "20" is specified and **DesiredResults** is set to "Higher", then the critical limit is reached when the category is below target by 20%. This field is maintained in the **S&OP Annual Plan**, **S&OP Constraint Annual Plan**, **SCM Targets**, and **SCM Constraint Targets** workbooks in RapidResponse. Other workbooks in RapidResponse then use these limits to determine when metric values should display with critical conditional formatting (typically, red). **Note:** This field is applicable when **Type.ProcessingRule** is set to "Target".	Quantity	

Table 6.119: HistoricalDemandCategory (Mfg) fields

Field name	Description	Data type	Key
Description	A description of this historical demand category.	String	
DesiredResults	This setting is used to indicate whether a high or low metric value, relative to the category's target, is considered desirable. It also determines how the **CriticalLimit** and **WarningLimit** values are applied against the target when determining if the critical and warning limits have been reached. Valid values are: • **High**—Metric values above their target are considered desirable (for example, revenue values). Thus critical and warning limits are triggered when metric values are below target. • **Low**—Metric values below their target are considered desirable for this category (for example, inventory levels). Thus critical and warning limits are triggered when metric values are above target. **Default Value:** High **Note:** This field is applicable when **Type.ProcessingRule** is set to "Target".	String (Enum)	
Type	The type of demand data this category contains. **Referenced table:** HistoricalDemandCategoryType	Reference	
Value	The name of this historical demand category.	String	Yes
WarningLimit	Indicates the warning level for metric values in this historical demand category expressed as a percentage of their target values. The interpretation of the value provided here depends on the setting in the **DesiredResults** field. If set to "Higher", then the warning limit is reached when below target by the percentage specified here. But if set to "Lower", then the warning limit is reached when above target by the percentage specified here For example, if a value of "5" is specified and **DesiredResults** is set to "Lower", then the warning limit is reached when the category is above target by 5%. This field is maintained in the **S&OP Annual Plan**, **S&OP Constraint Annual Plan**, **SCM Targets**, and **SCM Constraint Targets** workbooks in RapidResponse. Other workbooks in RapidResponse then use these limits to determine when metric values should display with warning conditional formatting (typically, yellow). **Note:** This field is applicable when **Type.ProcessingRule** is set to "Target".	Quantity	

HistoricalDemandCategory table – calculated and set fields

The following describes the calculated and set fields in the **HistoricalDemandCategory** table. For an introduction to this table, and descriptions of its input fields, see "HistoricalDemandCategory table" on page 329.

Table 6.120: Calculated HistoricalDemandCategory (Mfg) fields

Field name	Description	Data type	Key
Forecast Disaggregation ParametersActual Categories	Set of **ForecastDisaggregationParameter** records that reference this category as the actual category to use when calculating disaggregation parameters.	Set	
Forecast Disaggregation ParametersBy ActualCategory	Set of **ForecastDisaggregationParametersBy Category** records that reference this category as the actual category to use when calculating disaggregation parameters.	Set	
Forecast Disaggregation ParametersBy Category	Set of **ForecastDisaggregationParametersBy Category** records that reference this category as the category for which disaggregation parameters are being defined.	Set	
ForecastItem Parameters Actuals Categories	Set of **ForecastItemParameters** records that reference this category as the historical actual demand category.	Set	
ForecastItem Parameters Forecast Categories	Set of **ForecastItemParameters** records that reference this category as the historical actual demand category.	Set	
ForecastSafety StockItem Mappings	Set of **SafetyStockItemMapping** records that use this record for the historical forecast category.	Set	
ForecastSafety StockItems	Set of **SafetyStockItem** records that use this record for the historical forecast category.	Set	
Historical DemandHeaders	Set of **HistoricalDemandHeader** records that reference this record.	Set	

Table 6.120: Calculated HistoricalDemandCategory (Mfg) fields

Field name	Description	Data type	Key
RollingWeight	Set of **HistoricalDemandCategoryRollingWeight** records associated with this demand category. **Note:** This field was added in Version 2016.2, Service Update 12.	Set	
SafetyStockItem Mappings	Set of **SafetyStockItemMapping** records that use this record for the historical demand category.	Set	
SafetyStockItems	Set of **SafetyStockItemMapping** records that use this record for the historical demand category.	Set	
SOPActuals Category	Set of **SOPAnalyticsConfiguration** records that use this demand category to calculate disaggregation rates.	Set	
SOPForecast Disaggregation OverrideCategories	Set of **SOPAnalyticsConfiguration** records that use this demand category to override the default category used to calculate disaggregation rates.	Set	

HistoricalDemandCategoryRollingWeight table

The **HistoricalDemandCategoryRollingWeight** table stores forecast weight records for forecast categories when using rolling forecast weights to create the consensus demand plan. Each record in this table applies to a forecast category and indicates the weight given to that forecast category for a specific horizon. If a header has existing **HistoricalDemandHeaderTimephasedAttributes**, **HistoricalDemandHeaderRollingWeight**, or **HistoricalDemandHeader** records, this table is ignored. This table is also ignored if **CalcForecastStartDate** or **CycleCalendar** are undefined in the **SOPAnalyticsConfiguration** table.

The **HistoricalDemandCategoryRollingWeight** table supports the Demand Planning application in RapidResponse. Values in this table are maintained using the both the Control Tables and S&OP Demand Planning Ratios workbooks in RapidResponse. For more information about the Demand Planning application, see the RapidResponse Applications Guide.

This table was added in Version 2016.2, Service Update 12.

Table 6.121: HistoricalDemandCategoryRollingWeight (Mfg) fields

Field name	Description	Data type	Key
Category	A reference to the demand category that is associated with this **ConsensusForecastWeight**. **Referenced table**: HistoricalDemandCategory	Reference	Y
Horizon	A reference to the horizon that is set for this **ConsensusForecastWeight** for this demand category. **Referenced table**: ConsensusForecastRollingHorizon	Reference	Y
ConsensusForecast Weight	Specifies a weight as a percentage to apply to a given forecast category when generating the consensus forecast (as reported in the **ConsensusForecast** table and used to drive demand planning in RapidResponse). This field should typically contain values between 0 and 100. When generating the consensus forecast for a given part and customer combination, the **ForecastDetail.Quantity** value associated with each forecast category on a given date is multiplied by the value in this field, and the results are summed together. For example, if the Marketing and Finance forecast categories both had this field set to 20%, and all other categories were set to 0, the consensus forecast would be the sum of twenty percent of each of the marketing and finance forecasts. Within the effective horizon, a value provided in this field will override the values provided for the category in the **ConsensusForecastWeight** field in either of the **HistoricalDemandHeader** or **HistoricalDemandHeaderCategory** tables. **Default value**: -1 **Note:** For more information about how the consensus forecast is calculated, see ConsensusForecast table.	Quantity	

HistoricalDemandHeader table

This table identifies each unique part, customer, and historical demand category combination, and can be used to specify the weights associated with forecast categories when generating the consensus forecast for a particular part customer. Typically, it is referenced by multiple groups of historical demand actuals, forecasts, and other items.

If the **HistoricalDemandHeader** table contains a record for a given forecast category and part customer combination, and there is no effective record for that combination in either the **HistoricalDemandHeaderTimePhasedAttributes** table or the **HistoricalDemandHeaderRollingWeight** table, then the category weight is taken from this table.

This table supports Sales and Operations Planning, Demand Planning, and Statistical Forecasting in RapidResponse.

Table 6.122: HistoricalDemandHeader (Mfg) fields

Field name	Description	Data type	Key
Category	A reference to the demand category associated with this group of historical demands. **Referenced table**: HistoricalDemandCategory **Reference Syntax**: HistoricalDemandCategory	Reference	Yes
Consensus Forecast Weight	Specifies a weight to apply to the referenced forecast category for this part and customer combination when generating the consensus forecast (as reported in the **ConsensusForecast** table and used to drive supply planning in RapidResponse). The weight should be a value between 0 and 1. When generating the consensus forecast for a given part and customer combination, the **ForecastDetail.Quantity** value associated with each forecast category on a given date is multiplied by the value in this field, and the results are summed together. As such, only categories where this field is greater than zero are included in the consensus forecast calculation. For example, if the Marketing and Statistical forecast categories both had this field set to .5, and all other categories were set to 0, the consensus forecast would be the sum of fifty percent of each of the marketing and statistical forecasts. If time-phased weights per forecast category and part customer combination are required, the **HistoricalDemandHeaderTimePhasedAttributes** table can be used instead, and values in its ConsensusForecastWeight field override those in this table (within their effective date ranges). If consensus forecast weights are not provided for a given forecast category and part customer combination in either of these tables, then the ConsensusForecastWeight field value from the **HistoricalDemandHeaderCategory** table is used instead. **Default value:** -1 (indicates to ignore this field and use HistoricalDemandHeader.Category.ConsensusForecastWeight field value instead).	Quantity	
PartCustomer	The part and customer combination associated with this group of historical demands. **Referenced table**: PartCustomer **Reference Syntax**: PartCustomer.Part.Name, PartCustomer.Part.Site, PartCustomer.Customer	Reference	Yes

HistoricalDemandHeader table – calculated and set fields

The following describes the calculated and set fields in the **HistoricalDemandHeader** table. For an introduction to this table, and descriptions of its input fields, see "HistoricalDemandHeader table" on page 334.

If you have upgraded from RapidResponse 2014.2 (or earlier) to RapidResponse 2014.4 (or later) and your company has not converted the five standard tables to contain vector data, the following differences exist in this table:

- The Actuals field is a set, not a vector set.
- The ForecastDetails field is a set, not a vector set.

Table 6.123: Calculated HistoricalDemandHeader (Mfg) fields

Field name	Description	Data type	Key
Actuals	The **HistoricalDemandActual** records associated with this historical demand header.	Vector Set	
Consensus Forecast WeightByHeader	The **ConsensusForecastWeightByHeader** records associated with this historical demand header.	Set	
ForecastDetails	The **ForecastDetail** records associated with this historical demand header.	Vector Set	

HistoricalDemandHeaderRollingWeight table

The **HistoricalDemandHeaderRollingWeight** table stores the weight that is applied to a header for a specific duration of the horizon when using rolling forecast weights to create the consensus demand plan. If a header has existing **HistoricalDemandHeaderTimephasedAttributes** records, this table is ignored. This table is also ignored if **CalcForecastStartDate** or **CycleCalendar** are undefined in the **SOPAnalyticsConfiguration** table.

The **HistoricalDemandHeaderRollingWeight** table supports the Demand Planning application in RapidResponse. Values in this table are maintained using the both the **Control Tables** and **S&OP Demand Planning Ratios** workbooks in RapidResponse. In addition, the value of the **ForecastStartOffset** field in the **SOPAnalyticsConfiguration** table impacts how the remainder horizon period is calculated in the **Rolling Weight Summary** worksheet (**S&OP Demand Planning Ratios** workbook). If the value is >0, the remainder period starts at month 0 (and then continues after all other defined rolling horizons have ended). If the value = 0, the remainder period starts only after all other defined horizons have ended. For more information about the Demand Planning application, see the RapidResponse Applications Guide.

This table was added in Version 2016.2, Service Update 12.

Table 6.124: HistoricalDemandHeaderRollingWeight (Mfg) fields

Field name	Description	Data type	Key
Header	A reference to the header to which this rolling weight record applies. **Referenced table**: HistoricalDemandHeader **Referenced syntax**: Header.PartCustomer.Part.Name, Header.PartCustomer.Part.Site, Header.PartCustomer.Customer, HeaderCategory	Reference	Y
Horizon	A reference to the horizon that is set for this **ConsensusForecastWeight** for this demand category. **Referenced table**: ConsensusForecastRollingHorizon	Reference	Y
ConsensusForecastWeight	Specifies a weight as a percentage to apply to a given header when generating the consensus forecast (as reported in the **ConsensusForecast** table and used to drive demand planning in RapidResponse). This field should typically contain values between 0 and 100. Within the effective horizon, a value provided in this field will override the values provided for the category in the **ConsensusForecastWeight** field in either of the **HistoricalDemandHeader** or **HistoricalDemandHeaderCategory** tables. **Default value**: -1 **Note:** For more information about how the consensus forecast is calculated, see ConsensusForecast table.	Quantity	

HistoricalSupplyOrder table

This table stores historical supply orders, and is used for reporting historical supply.

This table was added in the Version 2016.2, Service Update 5, to support the Distribution Requirements Planning application.

Table 6.125: HistoricalSupplyOrder (Solutions) fields

Field name	Description	Data type	Key
CreatedDate	The date the supply order was created.	Date	
Id	A string identifier for the historical supply order.	String	Yes
Site	The site associated with the supply order. **Referenced table**: Site	Reference	Yes
Type	A type used to categorize this supply order.	String	Yes

HistoricalDemandHeaderTimePhased Attributes table

This **HistoricalDemandHeaderTimePhasedAttributes** table can be used if time-phased attributes are to be used when generating the consensus forecast during the sales and operations planning process in RapidResponse. Each record in this table applies to a specific part, customer, and forecast category combination, and indicates the weight given to that forecast category when generating the consensus forecast within the effective date range. If time-phased forecast weights are not required, this table can be ignored and the weight used for a given forecast category will be taken from the value in either the **HistoricalDemandHeader.ConsensusForecastWeight** field (if populated) or else the value in the **HistoricalDemandHeader.Category.ConsensusForecastWeight** field.

Table 6.126: HistoricalDemandHeaderTimePhasedAttributes (Mfg) fields

Field name	Description	Data type	Key
Consensus Forecast Weight	Specifies a time-phased weight to apply to a given forecast category for a part and customer combination when generating the consensus forecast (as reported in the **ConsensusForecast** table and used to drive supply planning in RapidResponse). This field should typically contain values between 0 and 1. When generating the consensus forecast for a given part and customer combination, the **ForecastDetail.Quantity** value associated with each forecast category on a given date is multiplied by the value in this field, and the results are summed together. For example, if the Marketing and Finance forecast categories both had this field set to 0.5, and all other categories were set to 0, the consensus forecast would be the sum of fifty-percent of each of the marketing and finance forecasts. Within the effective date range, a value provided in this field will override the values provided for the category in the **ConsensusForecastWeight** field in either of the **HistoricalDemandHeader** or **HistoricalDemandHeaderCategory** tables. Default value: 0 **Note:** For more information about how the consensus forecast is calculated, see "ConsensusForecast table" on page 966.	Quantity	
EffectiveInDate	The date on which this attribute record becomes effective.	Date	
EffectiveOutDate	The date on which this attribute record is no longer effective.	Date	

Table 6.126: HistoricalDemandHeaderTimePhasedAttributes (Mfg) fields

Field name	Description	Data type	Key
Header	A reference to the part, customer, and category this attribute record applies to. Records in this table are only applicable when **Header.Category.Type.ProcessingRule** is set to "Forecast". **Referenced table:** HistoricalDemandHeader **Reference Syntax:** Header.PartCustomer.Part.Name, Header.PartCustomer.Part.Site, Header.PartCustomer.Customer, Header.Category	Reference	Yes
Id	A unique identifier for this record. Note that if there are multiple records with the same EffectiveInDate for a given part, customer, and category, the one with the largest ID will take precedence.	String	Yes

HistoricalDemandOrder table

This table stores historical demand orders, and is used for reporting historical demands.

Table 6.127: HistoricalDemandOrder (Solutions) fields

Field name	Description	Data type	Key
CreatedDate	The date the demand order was created.	Date	
Id	Identifies the historical demand order.	String	Yes
Site	The site where the demand order was created. **Referenced table:** Site	Reference	Yes

HistoricalDemandOrder table – calculated fields

The following describes the calculated fields in the HistoricalDemandOrder table. For an introduction to this table, see "HistoricalDemandOrder table" on page 339.

Table 6.128: Calculated HistoricalDemandOrder (Solutions) fields

Field name	Description	Data type	Key
HistoricalDemand Actuals	The set of **HistoricalDemandActual** records that refer to this demand order.	Set	

HistoricalDemandSeries table

This table contains one record for each HistoricalDemandHeader and particular AsOfDate (the date when the demand records were generated) and Sequence (in cases where multiple series are generated on the same date). Each historical demand series entry corresponds to a collection of points that make up one set of historical demands (for a given part, customer, category, and as-of date).

This table supports Sales and Operations Planning in RapidResponse. It can be integrated during the initial RapidResponse deployment, and additional records are created as necessary through data change alerts in RapidResponse.

Table 6.129: HistoricalDemandSeries (Mfg) fields

Field name	Description	Data type	Key
AsOfDate	The date on which this historical demand series was generated.	Date	
Id	An identifier used to ensure uniqueness of this Header, AsOfDate, and Sequence combination.	String	Yes
Header	A reference to the part, customer, and demand category combination associated with this record. **Referenced table**: HistoricalDemandHeader **Reference Syntax**: Header.PartCustomer.Part.Name, Header.PartCustomer.Part.Site, Header.PartCustomer.Customer, Header.Category	Reference	Yes
Sequence	In cases where there is more than one series of historical demands for a part, customer, and demand category combination on a given AsOfDate, this field is used to identify each series. The first series on a given AsOfDate should have the lowest Sequence value, and the last series on a given AsOfDate should have the highest Sequence value.	Integer	

HistoricalDemandSeries table – calculated and set fields

The following describes the calculated and set fields in the HistoricalDemandSeries table. For an introduction to this table, see "HistoricalDemandSeries table" on page 340.

If you have upgraded from RapidResponse 2014.2 (or earlier) to RapidResponse 2014.4 (or later) and your company has not converted the five standard tables to contain vector data, the following differences exist in this table:

- The Details field is a set, not a vector set.

Table 6.130: HistoricalDemandSeries calculated (Mfg) fields

Field name	Description	Data type	Key
Details	The set of **HistoricalDemandSeriesDetail** records associated with this historical demand series header.	Vector Set	
FirstOnAsOfDate	Indicates if this HistoricalDemandSeries is the first one for a given Header and AsOfDate (has the lowest Sequence value). This field can be used in reports to allow filtering that shows only the first series for each AsOfDate. It is always set to 'Y' (yes) if a given Header and AsOfDate has only one series. Valid values are: • Y • N	Boolean	
IsBaseline	Indicates if this HistoricalDemandSeries is a baseline series for the associated part customer. A baseline series is one where the LastOnAsOfDate = 'Y' and the AsOfDate belongs to Header.PartCustomer.ToleranceProfile.BaselineCalendar. Valid values are: • Y • N	Boolean	
LastOnAsOfDate	Indicates if this HistoricalDemandSeries is the last one for a given Header and AsOfDate (has the highest Sequence value). This field can be used in reports to allow filtering that shows only the last series for each AsOfDate. It is always set to 'Y' (yes) if a given Header and AsOfDate has only one series. Valid values are: • Y • N	Boolean	
Number	Numbers each historical demand series from 0 to N, where the most recent series has a value of 0 and the oldest series has a value of N. This field can be used in reports to compare points in the latest historical demand series to points in the previous historical demand series.	Integer	

HistoricalDemandSeriesDetail table

This table contains an entry for each unique quantity and date interval combination in a historical demand series. It contains one entry for each non-zero point in a historical demand series.

Note: If you are entering past due amounts in the **HistoricalDemandSeriesDetail** table, it is important to insert all past due amounts into the current bucket. This will ensure that the data is correctly calculated by the **HistoricalDemandWaterfall** table.

This table supports Sales and Operations Planning in RapidResponse. It can be integrated during the initial RapidResponse deployment, and additional values from the ForecastDetail table are added to this table by the Insert Demand Planning History alerts in RapidResponse.

This table contains vector set data for records in the **HistoricalDemandSeries** table. For more information about vectors, see "Vector data" on page 138.

If you have upgraded from RapidResponse 2014.2 (or earlier) to RapidResponse 2014.4 (or later) and your company has not converted the five standard tables to contain vector data, the following differences exist in this table:

- The BeginDate field is not a key field.
- The EndDate field is not a key field.
- The Series field is a reference, not an owning reference.

You can determine whether this table is using vector data by opening the Data Model dialog box and reviewing table icons. Tables that contain vector data are displayed with the icon.

Table 6.131: HistoricalDemandSeriesDetail (Mfg) fields

Field name	Description	Data type	Key
BeginDate	The begin date of the interval to which this historical demand applies.	Date	Yes
EndDate	The end date of the interval to which this historical demand applies. This value should be greater than or equal to BeginDate. In delta calculations for the **HistoricalDemandWaterfall** table, EndDate is treated inclusively (that is, the interval covered by this historical demand includes this EndDate.)	Date	Yes
Quantity	The historical demand quantity for this interval. The value in this field is used if **HistoricalDemandCategory.UnitType = 'Quantity'**. For more information, see "HistoricalDemandCategory table" on page 329.	Quantity	
Series	A reference to the historical demand series that a given data point belongs to. **Referenced table:** HistoricalDemandSeries **Reference Syntax:** Series.Header.PartCustomer.Part.Name, Series.Header.PartCustomer.Part.Site, Series.Header.PartCustomer.Customer, Series.Header.Category, Series.Id	Reference (Owning)	Yes
UnitPrice	The unit price associated with this historical demand. This field is useful for calculating the revenue associated with historical demands.	Money	

Table 6.131: HistoricalDemandSeriesDetail (Mfg) fields

Field name	Description	Data type	Key
Value	The monetary value associated with this historical demand. The value in this field is used if **HistoricalDemandCategory.UnitType = 'Value'**. For more information, see "HistoricalDemandCategory table" on page 329.	Money	

Note: For an introduction to historical tables, see "Historical tables" on page 134.

HistoricalPartKPI table

The **HistoricalPartKPI** table contains part-based historical key performance indicator data. It supports RapidResponse applications that show inventory trends over time.

Data is not directly imported into this table. Instead it is populated by automatic data modifications (workbook commands) that archive results. To ensure unit of measure conversions work properly, when entering values for a key performance indicator that measures a quantity, you should typically ensure that the **KPI.EnableUOM** is set to "Yes" in the automatic data modification.

Notes:

- Data from this table was formerly used by the Risk/Opportunity Assessment workbook to display graphs. This table was populated by automatic data modifications that archived results associated with different key performance indicators in the Risk/Opportunity Assessment workbook. Data was not be directly imported into this table. In RapidResponse 11.0, the Risk/Opportunity Assessment workbook was modified to remove support for historical KPI information. If your company is using the RapidResponse 10.1 (or earlier) version of this workbook then this table continues to use the key performance indicators listed in the following table.
- For more information about historical tables, see "Historical tables" on page 134.

Table 6.132: HistoricalPartKPI (Mfg) fields

Field name	Description	Data type	Key
Date	The date associated with this key performance indicator value.	Date	
KPI	The key performance indicator with a historical data value saved in this record. Each record should reference one of the following KPI values: • OnHandNetttable • OnHandNonNettable • OnTimeHistory • OnTimeHistoryRequest • ServiceLevelTarget • TotalDemand • TotalHistory • TotalSupply **Referenced table:** KPI **Reference Syntax**: KPI.Value	Reference	Yes
Part	The part that this key performance indicator value applies to. **Referenced table:** Part **Reference Syntax:** Part.Name, Part.Site	Reference	Yes
Quantity	The value associated with this key performance indicator for the given part and date combination.	Quantity	

The following KPIs were used by the Risk/Opportunity Assessment workbook.

- Excess$
- NumberAllocationIntegrity
- NumberBOMIntegrity
- NumberCancels
- NumberExpedites
- NumberIDIntegrity
- NumberNewPlannedOrders
- NumberPartMasterIntegrity
- NumberPartSourceIntegrity
- NumberPushes
- NumberSRIntegrity
- Obsolete$
- OrdersAtRiskQuantity
- OrdersAtRisk$
- PurchaseAvoidanceQty
- PurchaseAvoidance$

- RevenueOpportunitiesQty
- RevenueOpportunities

HistoricalReceipt table

This table contains historical receipt information relating to yields used by the Self-Healing Supply Chain.

Table 6.133: HistoricalReceipt (Mfg) fields

Field name	Description	Data type	Key
Header	A reference to the "HistoricalReceiptHeader table" on page 345.	Reference	Yes
LineReceivedDate	The actual date of receipt.	Date	Yes
Id	The ID value. This may be a concatenated string based on key fields.	String	Yes
StartQuantity	The supply quantity before yield adjustment. Values less than 0 are considered invalid.	Money	
ReceivedQuantity	The supply quantity after yield adjustment. Values less than 0 are considered invalid.	Quantity	

Note: For an introduction to historical tables, see "Historical tables" on page 134.

HistoricalReceipt table – calculated and set fields

The following describes the calculated and set fields in the **HistoricalReceipt** table.

Table 6.134: Calculated HistoricalReceipt (Mfg) fields

Field name	Description	Data type	Key
CalcYieldRatio	Calculated field. Reports the ratio: ReceivedQuantity / StartQuantity. If input is invalid, this field reports -1.	Quantity	

HistoricalReceiptHeader table

This table identifies each unique part, supplier, and historical supply category combination. Each of the entries in this table are typically associated with multiple historical supply series or historical receipt records.

Table 6.135: HistoricalReceiptHeader (Mfg) fields

Field name	Description	Data type	Key
BOMAlternate	Reference to BOMAlternate, to support different product versions.	Reference	Yes
Category	A reference to the historical supply category associated with this group of historical supplies. **Referenced table**: HistoricalSupplyCategory **Reference Syntax**: HistoricalSupplyCategory	Reference	Yes
PartSupplier	The part and supplier combination associated with this group of historical supplies. **Referenced table**: PartSupplier **Reference Syntax**: Part.Name, PartSupplier.Part.Site, PartSupplier.Supplier	Reference	Yes
Routing	Reference to Routing, to support different product versions.	Reference	Yes
Source	Nullable reference to Source.	Reference	Yes

Note: For an introduction to historical tables, see "Historical tables" on page 134.

HistoricalShipment table

This table stores historical shipments, and is used for reporting historical shipping data for the Distribution Requirements Planning application.

This table was added in the Version 2016.2, Service Update 5, to support the Distribution Requirements Planning application.

Table 6.136: HistoricalShipment (Solutions) fields

Field name	Description	Data type	Key
CreatedDate	The date the shipment was created.	Date	
Id	A string identifier for this historical shipment.	String	Yes
Site	The site associated with the shipment. **Referenced table**: Site	Reference	Yes

HistoricalSupplyActual table

This table contains supply data related to historical actual orders placed against suppliers on a given date.

This table contains vector set data for records in the **HistoricalSupplyHeader** table. For more information about vectors, see "Vector data" on page 138.

If you have upgraded from RapidResponse 2014.2 (or earlier) to RapidResponse 2014.4 (or later) and your company has not converted the five standard tables to contain vector data, the following differences exist in this table:

- The Date field is not a key field.
- The Header field is a reference, not a key reference.

You can determine whether this table is using vector data by opening the Data Model dialog box and reviewing table icons. Tables that contain vector data are displayed with the icon.

Table 6.137: HistoricalSupplyActual (Mfg) fields

Field name	Description	Data type	Key
ActualDockDate	The actual date this supply arrived at the receiving dock, which is used in historical reporting. This field is in the **Solutions** namespace. **Note:** This field was added in Version 2016.2, Service Update 5	Date	
ActualShipDate	The actual date this supply was shipped from the supplier, which is used in historical reporting. This field is in the **Solutions** namespace. **Note:** This field was added in Version 2016.2, Service Update 5.	Date	
Date	The date associated with this actual shipment. The date used should be consistent with the historical supply series dates. For example, if the historical supply series dates represent the dates that parts ship from the dock, then this date should be a dock departure date. **Note:** If set to either Undefined, Past, or Future, then this record is ignored by safety stock calculations.	Date	Yes
HandlingCost	The cost associated with handling the shipment. Negative values are treated as zero. This field is in the **Solutions** namespace. **Note:** This field was added in Version 2016.2, Service Update 5.	Money	

Table 6.137: HistoricalSupplyActual (Mfg) fields

Field name	Description	Data type	Key
Header	A reference to the historical supply header associated with the record. This identifies the part, supplier, and supply category for this actual order. **Referenced table**: HistoricalSupplyHeader **Reference Syntax**: Header.PartSupplier.Part.Name, Header.PartSupplier.Part.Site, Header.Category	Reference (Owning)	Yes
LeadTime	The known lead time associated with this historical supply. Typically when both the **OrderDate** and **Date** fields are defined, the historical lead time value used in safety stock calculations where supply variability is assumed is calculated based on those two fields. However, if the **OrderDate** field is not provided, then the historical lead time value used in safety stock calculations is set to the value provided in this field. This value should be expressed in units of the **HistoricalSupplyHeader.LeadTimeCalendar** (otherwise, if that calendar is not defined, an "Everyday" calendar is assumed).	Integer	
LineDueDate	The date that the ScheduledReceipt (or purchase order) is expected from the supplier. For orders with multiple lines, this may be different dates per line. **Note:** This field was added in Version 2016.2, Service Update 26.	Date	
Order	A reference to the historical supply order number associated with this record. This field is in the **Solutions** namespace. **Referenced table:** HistoricalSupplyOrder **Note:** This field was added in Version 2016.2, Service Update 5.	Reference	
OrderDate	The date associated with the ordering of this supply. For parts configured as either single or multi-echelon safety stock items and where supply lead time variability is to be considered, the difference between the Date field and this value is typically used to determine historical supply lead times. If this value is undefined, or set to either 'past' or 'future', then the value in the **LeadTime** field is used during safety stock item calculations.	Date	

Table 6.137: HistoricalSupplyActual (Mfg) fields

Field name	Description	Data type	Key
OrderDueDate	Indicates the DueDate associated with a historical supply order. This field should be populated if using the MPS application, and is required by certain resources that report details such as schedule attainment. **Note:** This field is in the **Solutions** namespace.	Date	
Quantity	The number of units in this actual order.	Quantity	
ReceiptQuantity	The total amount that was received on this shipment record. This field is in the **Solutions** namespace. **Note:** This field was added in Version 2016.2, Service Update 5.	Quantity	
Shipment	A reference to the historical shipment associated with this record. This field is in the **Solutions** namespace. **Referenced table:** HistoricalShipment **Note:** This field was added in Version 2016.2, Service Update 5.	Reference	
ShippingCost	The cost associated with shipping the shipment. Negative values are treated as zero. This field is in the **Solutions** namespace. **Note:** This field was added in Version 2016.2, Service Update 5.	Money	
Source	A reference to the source that provided the part this historical supply record pertains to. This reference should typically be populated for parts belonging to multi-echelon families and for which variable lead time is enabled based on historical supply actuals. If a part has multiple sources of supply, this reference can help ensure the correct one is identified. **Referenced table:** Source (Nullable)	Reference	

Table 6.137: HistoricalSupplyActual (Mfg) fields

Field name	Description	Data type	Key
StatisticalDate	The date that the buyer uses to track the agreed-upon delivery date from the supplier. In the case where the buyer has asked to delay a shipment, then the StatisticalDate will be adjusted to match the updated LineDueDate. In the case where the supplier has identified that they will deliver late, then the StatisticalDate remains unchanged, but the LineDueDate will be adjusted to the new expected delivery date. **Note:** This field was added in Version 2016.2, Service Update 26.	Date	
UnitPrice	The unit price for the historical supply. This value can be used to calculate the cost associated with historical actual supplies. The default value for **HistoricalSupplyActual.UnitPrice** is 0.	Money	

Note: For an introduction to historical tables, see "Historical tables" on page 134.

HistoricalSupplyCategory table

This table identifies both different categories of historical supply series and historical supply actuals. It is used to categorize values in both the **HistoricalSupplyActual** and **HistoricalSupplySeries** tables.

Table 6.138: HistoricalSupplyCategory (Mfg) fields

Field name	Description	Data type	Key
Description	A description of this historical supply category.	String	
Value	The name of this historical supply category.	String	Yes

HistoricalSupplyCategory table – calculated and set fields

The following describes the calculated and set fields in the **HistoricalSupplyCategory** table.

Table 6.139: HistoricalSupplyCategory calculated (Mfg) fields

Field name	Description	Data type	Key
HistoricalSupplyHeaders	A set of calculated **HistoricalSupplyHeader** records associated with this **HistoricalSupplyCategory**. **Referenced table:** "HistoricalSupplyHeader table" on page 351	Set	
ItemSourceHistoricalSupplyCategorys	A set of calculated **ItemSourceHistoricalSupplyCategory** records associated with this **HistoricalSupplyCategory**. **Referenced table:** "ItemSourceHistoricalSupplyCategory table" on page 389	Set	
MEIOLeadTimeTypes	A set of calculated **MEIOLeadTimeType** records associated with this **HistoricalSupplyCategory**. **Referenced table:** "MEIOLeadTimeType table" on page 744	Set	
SafetyStockItemMappings	A set of calculated **SafetyStockItemMapping** records associated with this **HistoricalSupplyCategory**. **Referenced table:** "SafetyStockItemMapping table" on page 554	Set	
SafetyStockItems	A set of calculated **SafetyStockItem** records associated with this **HistoricalSupplyCategory**. **Referenced table:** "SafetyStockItem table" on page 541	Set	

Note: For an introduction to historical tables, see "Historical tables" on page 134.

HistoricalSupplyHeader table

This table identifies each unique part, supplier, and historical supply category combination. Each of the entries in this table are typically associated with multiple historical supply series or historical supply actual records.

Table 6.140: HistoricalSupplyHeader (Mfg) fields

Field name	Description	Data type	Key
Category	A reference to the historical supply category associated with this group of historical supplies. **Referenced table**: HistoricalSupplyCategory **Reference Syntax**: HistoricalSupplyCategory	Reference	Yes
LeadTime Calendar	The calendar used to express known lead times associated with historical supply actuals under this header. That is, if **HistoricalSupplyActual.LeadTime** is populated, it is assumed to be in intervals of this calendar. The **LeadTime** field is used in safety stock calculations that assume historical lead time variability, but where the **OrderDate** is not provided and therefore historical lead time cannot be calculated. If this reference is left Null, then an "Everyday" calendar is assumed. **Referenced table**: Calendar (Nullable)	Reference	
PartSupplier	The part and supplier combination associated with this group of historical supplies. **Referenced table**: PartSupplier **Reference Syntax**: Part.Name, PartSupplier.Part.Site, PartSupplier.Supplier	Reference	Yes

Note: For an introduction to historical tables, see "Historical tables" on page 134.

HistoricalSupplyHeader table – calculated and set fields

The following describes the calculated and set fields in the **HistoricalSupplyHeader** table. For an introduction to this table, and descriptions of its input fields, see "HistoricalSupplyHeader table" on page 351.

If you have upgraded from RapidResponse 2014.2 (or earlier) to RapidResponse 2014.4 (or later) and your company has not converted the five standard tables to contain vector data, the following differences exist in this table:

- The Actuals field is a set, not a vector set.

Table 6.141: Calculated HistoricalSupplyHeader (Mfg) fields

Field name	Description	Data type	Key
Actuals	The **HistoricalSupplyActual** records associated with this historical supply header.	Vector Set	

HistoricalSupplySeries table

This table contains one record for each HistoricalSupplyHeader and particular AsOfDate (the date when the supply records were generated) and Sequence (in cases where multiple series were generated on the same date). Each historical supply series entry corresponds to a collection of points that make up one set of historical supplies (for a given part, supplier, category, and as-of date).

Table 6.142: HistoricalSupplySeries (Mfg) fields

Field name	Description	Data type	Key
AsOfDate	The date on which this historical supplier series was generated.	Date	
Id	An identifier used to ensure uniqueness of this Header, AsOfDate, and Sequence combination.	String	Yes
Header	A reference to the part, supplier, and supply category combination associated with this record. **Referenced table**: HistoricalSupplyHeader **Reference Syntax**: Header.PartSupplier.Part.Name, Header.PartSupplier.Part.Site, Header.PartSupplier.Supplier, Header.Category	Reference	
Sequence	In cases where there is more than one series of historical supplies for a part, supplier, and supply category combination on a given AsOfDate, this field is used to identify each series. The first series on a given AsOfDate should have the lowest Sequence value, and the last series on a given AsOfDate should have the highest Sequence value.	Integer	

Note: For an introduction to historical tables, see "Historical tables" on page 134.

HistoricalSupplySeries table – calculated and set fields

The following describes the calculated fields in the HistoricalSupplySeries table. For an introduction to this table, see "HistoricalSupplySeries table" on page 353.

If you have upgraded from RapidResponse 2014.2 (or earlier) to RapidResponse 2014.4 (or later) and your company has not converted the five standard tables to contain vector data, the following differences exist in this table:

- The Details field is a set, not a vector set.

Table 6.143: HistoricalSupplySeries (Mfg) calculated fields

Field name	Description	Data type	Key
FirstOnAsOfDate	Indicates if this HistoricalSupplySeries is the first one for a given Header and AsOfDate (has the lowest Sequence value). This field can be used in reports to allow filtering that shows only the first series for each AsOfDate. It is always set to 'Y' (yes) if a given Header and AsOfDate has only one series. Valid values are: • Y • N	Boolean	
IsBaseline	Indicates if this HistoricalSupplySeries is a baseline series for the associated part supplier. A baseline series is one where the LastOnAsOfDate = 'Y' and the AsOfDate belongs to Header.PartSupplier.ToleranceProfile.BaselineCalendar. Valid values are: • Y • N	Boolean	
LastOnAsOfDate	Indicates if this HistoricalSupplySeries is the last one for a given Header and AsOfDate (has the highest Sequence value). This field can be used in reports to allow filtering that shows only the last series for each AsOfDate. It is always set to 'Y' (yes) if a given Header and AsOfDate has only one series. Valid values are: • Y • N	Boolean	
Number	Numbers each historical supply series from 0 to N, where the most recent series has a value of 0 and the oldest series has a value of N. This field can be used in reports to compare points in the latest historical supply series to points in the previous historical supply series.	Integer	
Details	The set of HistoricalSupplySeriesDetail records associated with this historical supply series.	Vector Set	

Note: For an introduction to historical tables, see "Historical tables" on page 134.

HistoricalSupplySeriesDetail table

This table contains an entry for each unique quantity and date interval combination in a historical supply series. It contains one entry for each non-zero point in a historical supply series.

This table contains vector set data for records in the **HistoricalSupplySeries** table. For more information about vectors, see "Vector data" on page 138.

If you have upgraded from RapidResponse 2014.2 (or earlier) to RapidResponse 2014.4 (or later) and your company has not converted the five standard tables to contain vector data, the following differences exist in this table:

- The BeginDate field is not a key field.
- The EndDate field is not a key field.
- The Series field is a reference, not an owning reference.

You can determine whether this table is using vector data by opening the Data Model dialog box and reviewing table icons. Tables that contain vector data are displayed with the icon.

Table 6.144: HistoricalSupplySeriesDetail (Mfg) fields

Field name	Description	Data type	Key
BeginDate	The begin date of the interval to which this historical supply applies.	Date	Yes
EndDate	The end date of the interval to which this historical supply applies. This value should be greater than or equal to BeginDate. In delta calculations for the **HistoricalSupplyWaterfall** table, EndDate is treated inclusively (that is, the interval covered by this historical demand includes this EndDate.)	Date	Yes
Quantity	The historical supply quantity for this interval.	Quantity	
Series	A reference to the historical supply series that a given data point belongs to. **Referenced table:** HistoricalSupplySeries **Reference Syntax:** Series.Header.PartSupplier.Part.Name, Series.Header.PartSupplier.Part.Site, Series.Header.PartSupplier.Supplier, Series.Header.Category, Series.Id	Reference (Owning)	Yes
UnitPrice	The unit price associated with this historical supply. This field is useful for calculating the cost associated with historical supplies.	Money	

Note: For an introduction to historical tables, see "Historical tables" on page 134.

HoldCode table

The **HoldCode** table contains hold codes assigned to customers and/or individual line items for the purpose of preventing orders from moving beyond a particular stage in the order fulfillment process. For example, a hold code might be created for a customer's credit issues and their orders not allowed to ship until the issue is resolved.

This table supports the Order Fulfillment application in RapidResponse.

Note: If a line item (from an **IndependentDemandSolution** record) and the customer on the order it belongs to (**DemandOrder.Customer** reference) both reference a valid **HoldCode** value, the code on the line item takes precedence. For example, if a customer is on credit hold and references a **HoldCode** that does not allow orders to ship, this can be overridden on an individual line item by referencing a **HoldCode** that does allow the order to ship.

Table 6.145: HoldCode (Solutions) fields

Field name	Description	Data type	Key
AllowScheduling	Indicates whether orders associated with this hold code are brought into the order promising process and a commitment made to the customer request. Valid values are: • **N**—orders are not brought into the order promising process. No order commitments are made to these customer requests which are treated as informational only. • **Y**—orders are brought into the order promising process. Order commitments are generated in response to the customer request dates.	Boolean	
AllowShip	Indicates whether an order associated with this hold code can be released for shipment to the customer. Valid values are: • **N**—orders using this hold code are flagged to indicate they should not be shipped. • **Y**—orders using this hold code can be shipped to the customer as normal.	Boolean	
Description	A description or purpose of the hold code. For example, the hold code might have been created to deal with customer credit problems or an issue at the customer's receiving location.	String	
Id	A unique string identifier for this hold code.	String	Key
Customers	Set of customers that are currently assigned this hold code.	Set	
Independent Demand Solutions	Set of independent demands (line items) that are currently assigned this hold code.	Set	

ImportedStatisticalForecast table

The **ImportedStatisticalForecast** table can be used to import statistical forecasts that were generated by an external tool or application (instead of having them calculated by a forecast model in

RapidResponse). This table contains vector set data for records in the **ForecastItemParameters** table, and each record added should specify a forecast date and quantity for the referenced forecast item.

The statistical forecast values imported into this table can then be used by all other subsequent RapidResponse forecast calculations. For example, NPI/EOL profiles can be applied to the imported forecast before corresponding records are added to the **StatisticalForecast** table, and disaggregation logic can be applied to those values before being added to the **StatisticalForecastDetail** table at the detailed part-customer level.

Note that in order for the records in this table to be used by forecast logic, the referenced **ForecastItemParameters** record must have a **Type.ForecastModel** setting of "ForecastImport" (for all other settings, RapidResponse will generate the statistical forecast based on history and specified item-level parameters).

This table was added in Version 2016.2, Service Update 5.

Table 6.146: ImportedStatisticalForecast (Mfg) fields

Field name	Description	Data type	Key
Date	The date this forecast quantity applies to. Forecast values should be specified on dates belonging to the forecast item's **Type.IntervalsCalendar**. If a forecast is specified for a date not belonging to the item's **IntervalsCalendar**, it is automatically rounded back to the previous date that does belong to that calendar. Note also that forecast values should be specified on **IntervalsCalendar** dates starting after **SOPAnalyticsConfiguration.CalcHistoricalEndDate** and continuing for the number of intervals specified in **ForecastItemParameters.ForecastIntervalCount**. Any forecasts values imported outside of this range will be ignored (and intervals missing a forecast value are flagged with a warning).	Date	Yes
ItemParameters	A reference to the parameters associated with the forecast item for which this statistical forecast quantity is being imported. The parameters include those that would otherwise be used in generating the statistical forecast, as well as those applied to all statistical forecasts regardless of whether the forecast is generated or imported. The forecast item itself is also available through this reference. **Referenced table:** ForecastItemParameters **Reference syntax:** ItemParameters.ForecastCategory.Value ItemParameters.Item.Path	Reference (Owning)	Yes
Quantity	The quantity of the statistical forecast for the date specified. Note that any values less than zero, will be interpreted as zero (0).	Quantity	

IndependentDemand table

The **IndependentDemand** table identifies demand not directly related to demand for other parts. Demand for finished goods or services parts are examples of independent demand.

Table 6.147: IndependentDemand (Mfg) fields

Field name	Description	Data type	Key
Allotment Override	A reference to the allotment override reserving component supply to this demand. The reserved supply is allocated to any demand(s) referencing the allotment override before it can be made available to other demands. **Referenced table:** AllotmentOverride (Nullable)	Reference	
ConfirmByDate	Date by which this order should be confirmed, or its allocations may be released. Is not directly used in calculations, but is used by applications and can be used in reports to show orders to be confirmed.	Date	
Customer RequestDate	The date on which the customer wants to receive delivery of the order at their location. The Order Fulfillment application uses this date along with pick/pack and transit times to set the **RequestDate** (the date by which the order should be completed to stock in order to meet the customer request). However, this field is not currently used in any analytic calculations.	Date	
DeliveryRoute	A reference to the delivery route used to transport this order to the customer. Related details such as transit time and carrier responsible for the delivery are available from this reference. **Referenced table:** DeliveryRoute (Nullable)	Reference	
DueDate	The date the order is scheduled to be completed to stock. **Default value**: Future **Note:** If the date is 'Undefined', the demand is ignored.	Date	

Table 6.147: IndependentDemand (Mfg) fields

Field name	Description	Data type	Key
ExpiryOffset	Allows for the expiry requirements placed on component ingredients to be adjusted (reduced) on a demand by demand basis. It specifies the number of **Part.PlanningCalendars.ExpiryCalendar** intervals to extend the minimum shelf life, and hence the calculated **EarliestExpiryDate**, before exploding demand down to the item's components. Thus, the expiry date on supplies used to satisfy the demand must then satisfy this adjusted earliest expiry date. When calculated expiry dates are subsequently rolled back up the product structure, the **SupplyDemand**.**ExpiryDate** on the record reporting an allotment of supply to this top level demand is then adjusted (reduced) by the value in this field. This ensures that the **ExpiryDate** reflects the limiting and demand-specific expiry requirements on the rolled up components. Note that this field is only applicable on records for which the **MinimumShelfLife** value is provided (ignored when **MinimumShelfLife** is taken from the **Part** record). **Default value:** -1	Integer	
InputPool	The pool to which this independent demand line belongs. This field supports inventory pooling as well as forecast consumption by pool. It is used only when **Part.MUEPoolNettingType.PoolRule** is set to a value other than "Ignore". If this field is left Null, then the pool from **Order.Pool** is used instead. Typically, this field should be used when the pools applicable to demands do not easily correspond to the order level. For example, it should be used if pools are meant to represent specific areas like a plant or storage location. However, if pools are meant to represent customers, or other order-level items, then this value might be left Null and the pool from the **DemandOrder** record will be used instead. **Referenced table:**Pool (Nullable) **NOTE**: This field was added in Version 2016.2, Service Update 19	Reference	
Line	A unique identifier associated with each IndependentDemand record with the same Order.Id. **Default value**: blank string	String	Yes

Table 6.147: IndependentDemand (Mfg) fields

Field name	Description	Data type	Key
MinimumShelf Life	This field specifies the number of **Part.PlanningCalendars.ExpiryCalendar** intervals that are added to the demand's **DueDate** when calculating its **EarliestExpiryDate**. The EarliestExpiryDate is the date before which supplies must not expire if they are to be allocated to the demand. For example, if the DueDate is July 1 2009, Part.PlanningCalendars.ExpiryCalendar is set to "Everyday", and this value is set to "21", then the EarliestExpiryDate would be set to July 22, 2009 (that is, any supply expiring before July 22, 2009 cannot be used to satisfy the demand). When this field is undefined (set to a value less than zero), then the **Part.MinimumShelfLife** is used in calculating the EarliestExpiryDate for the demand. **Default value:** -1	Integer	
Model	The model that is associated with this independent demand. Based on the **DemandStatus.ModelUsage** setting, either this model or the default model (the None model) is effective for the demand. The actual usage of the demand's effective model in analytic calculations is determined by the setting in **Part.MUEPoolNettingType.ModelRule.** This further depends on the Model-Unit Effectivity capability having been enabled. **Referenced table:** Model	Reference	
Order	A value that determines the processing policies of IndependentDemand. **Referenced table:** DemandOrder **Reference Syntax:** Order.Type, Order.Id, Order.Site	Reference	Yes
OrderPriority	The priority associated with this demand. **Referenced table:** OrderPriority	Reference	
Original RecordId	Identifies records that have been sent to your enterprise data sources in a closed-loop operation. This is a concatenation of the date the closed-loop operation was performed and the RecordId value for the record. When data is next updated, this value is compared to the new IndependentDemand records and ensures the records are not double-counted. The RecordId value is a number representing the sequence a record was created in. Each additional record added to the table increments the RecordId by one, and RecordId values are not reused when records are deleted. For more information about RecordId, see the *RapidResponse Resource Authoring Guide*. This field is in the **Solutions** namespace.	String	

Table 6.147: IndependentDemand (Mfg) fields

Field name	Description	Data type	Key
Part	Part for which the IndependentDemand exists. **Referenced table:** Part **Reference Syntax:** Part.Name, Part.Site	Reference	
PromisedDate	The date the part was promised for delivery to the customer receiving location. The difference between DueDate and this date represents pick/pack and transit time when reporting projected delivery date from AvailableDate. **Default value**: Undefined	Date	
ProtectQuantity	Indicates whether the value in the Quantity field is modified when data is edited in a grouped worksheet. This field is used in the Advanced Data Editing dialog box as part of the expression that determines which records are not edited when a grouped worksheet is edited. Valid values are: • **Y**—the Quantity cannot be modified in summarized worksheets. • **N**—the Quantity can be modified. For more information, see "Protect a record" in the *RapidResponse Resource Authoring Guide*. **Default value**: N	Boolean	
Quantity	The amount still to be delivered. Demands with negative quantities are ignored. **Default value**: 0	Quantity	
RequestDate	The date by which the order would need to be completed to stock in order to ensure it can be shipped in time to meet the customer's requested date. After all demands are initially planned to their scheduled due date, any demands that have **OrderPriority.TwoDatePlanningRule** set to "Use" are then moved towards their request date as possible. This allows for available dates that are closer to the original customer request date (and therefore potentially earlier than the committed due date). For more information about how this field is used in two-date planning logic, see "Two-date planning" on page 1803. **Default Value:** Undefined	Date	
SavedPriority	Duplicates OrderPriority, load with same data as OrderPriority. Not used by RapidResponse analytics, but may be used by RapidResponse legacy applications. **Referenced table:** OrderPriority	Reference	

Table 6.147: IndependentDemand (Mfg) fields

Field name	Description	Data type	Key
ShipmentPolicy	The shipment policy associated with this independent demand. It controls whether the quantity can be split into partial shipments, or if it must be shipped in its entirety. **Referenced table:** ShipmentPolicy **Note:** This field has no impact on any independent demands that belong to ship sets.	Reference	
ShippedQty	The quantity that has already been shipped. Negative quantities are ignored (treated as 0) by RapidResponse calculations. Note that if **DemandType.ProcessingRule** is set to "SalesActual", then this quantity can consume forecast (though is otherwise ignored by Netting). **Default value**: 0	Quantity	
ShipSet	A reference to the ship set, if any, this independent demand belongs to. All independent demands with the same Order and ShipSet value should ship together as a whole order. A blank value (that is, ' ') should be specified for independent demands not belonging to a ship set. **Referenced table:** ShipSet (this reference is nullable in new installations of RapidResponse 10.1 and later).	Reference	
StartUnit	The unit number to use for this independent demand. The StartUnit is applied to the entire demand, so the supply for this demand must have the same StartUnit. For example, if the demand has StartUnit=25 and Quantity=3, then all three units of supply will be for StartUnit=25 (and not for StartUnit=25, 26, and 27). Therefore, if using serial number (unit) control of netting or configuration, the Quantity should be 1 so that each unit will be planned and configured independently. This field is ignored unless the Model-Unit Effectivity is enabled, and the value of Part.MUEPoolNettingType.UnitRule is set to either “Net” or “Block”. **Default value**: -1	Integer	
Status	A reference to the DemandStatus table. **Referenced table:** DemandStatus	Reference	

Table 6.147: IndependentDemand (Mfg) fields

Field name	Description	Data type	Key
Transaction Sequence	The sequence of this demand. If demands have the same order priority and **MaintainCommitments** is set to 'Y' for the part, then supplies will be allocated by transaction sequence value (smallest to largest). **Note:** This field has no impact on any independent demands that belong to ship sets. **Note:** On startup, the server checks the maximum value for a transaction sequence number and if the value is greater than 0x30000000 hex (or 805306368 decimal), it will reset the sequence number back to zero and re-sequence all the ScheduledReceipt and IndependentDemand records.	Integer	
UnitSelling Price	The unit price for this line item. A negative value is a flag to calculate the unit selling price using the Quantity and the Part.AverageSellingPrice. **Default value**: 0	Money	

IndependentDemand table – calculated and set fields

The following describes the calculated and set fields in the IndependentDemand table. For an introduction to this table, and descriptions of its input fields, see "IndependentDemand table" on page 358.

Table 6.148: Calculated IndependentDemand (Mfg) fields

Field name	Description	Data type	Key
ActionParts Count	The number of action parts on this demand. An action part refers to any part with a supply pegged to this demand where the availability of that supply is contributing to the demand being late. For example, the supply might have a due date later than needed, or it might have a constraint that makes it unavailable in time.	Integer	
AvailableDate	The date at which the demand will actually be completed to stock in consideration of capacity, constraint, and material availability. If EffectiveDemand = 0, then this field reports a value of "Undefined".	Date	
AvailableReceipt Date	The date on which the order is now expected to be received at the customer destination. This is calculated by adding the applicable pick and pack time to **ShipSetAvailableDate**, offsetting to the next date on the delivery route's pickup calendar (or the Everyday calendar if a pickup calendar is not defined), and then adding transit time for the route.	Date	

Table 6.148: Calculated IndependentDemand (Mfg) fields

Field name	Description	Data type	Key
AvailableShip Date	The date on which the order will actually be available to ship to the customer. This is calculated by adding the applicable pick and pack time to **ShipSetAvailableDate** and then returning the next date on the delivery route's pickup calendar (or the Everyday calendar if a pickup calendar is not defined).	Date	
CostOfGoods Sold	The total rolled-up costs of goods sold from all component supplies used in satisfying this independent demand. This field summarizes the date-specific cost values reported in the **IndependentDemandCost** table and described on page "IndependentDemandCost table" on page 1073.	Money	
DaysLate	How late (in working days) this demand is expected to be.	Integer	
EarliestExpiry Date	The date before which a supply must not expire if is to be used in satisfying this demand. Calculated based on the demand **DueDate** and either the **MinimumShelfLife** and **ExpiryOffset** values (if the **MinimumShelfLife** value is greater than or equal to zero) or **Part.MinimumShelfLife**. When the **Part.Type.ExpiryRule** is set to "Ignore", then this field is always set to "Past".	Date	
EffectiveDemand	Effective demand quantity. The quantity of this demand actually used by netting. For MPS or MPSConfig type parts, if the record has **Order.Type.ProcessingRule** = 'SalesForecast', then EffectiveDemand is the portion of the forecast that is past the demand time fence and not consumed (and hence drives demand). This is the sum of UnconsumedQty of Forecast records linked to this IndependentDemand. For other parts, if **Order.Type.ProcessingRule** is 'SalesForecast' or 'Ignore', then EffectiveDemand is 0 (demand is ignored by netting). Similarly if **Part.Type.ProcessingRule** is set "Ignore" or if the part never has any valid part sources, than a value of 0 is also returned. **Note:** For orders left at least partially unsatisfied, this field will have also been reduced by the value reported in the UnsatisfiedQuantity field.	Quantity	

Table 6.148: Calculated IndependentDemand (Mfg) fields

Field name	Description	Data type	Key
EffectiveUnit Price	The unit price effective for the part and customer on the date this demand is due. This value is useful when calculating revenue, and is calculated as follows: • If IndependentDemand.UnitSellingPrice is greater than zero, that value is reported here. • Otherwise, RapidResponse checks the CustomerPrice table for records with matching Part and Customer values that have effective dates less than or equal to the demand due date. If any matching records are found, then the UnitPrice from the record with the latest effective date is reported here. Note that if multiple records exist for a given part and customer combination with the same effective date, the EffectiveUnitPrice calculation uses the record with the larger value in the CustomerPrice.Id field. • However, if no matching Part and Customer values are found, RapidResponse next checks the CustomerPrice table for records with a matching Part and blank Customer value (that is, ' ') that have effective dates less than or equal to the demand due date. If any matching records are found, then the UnitPrice from the record with the latest effective date is reported here. • Finally, if no unit price can be found under any of the conditions mentioned above, the value in Part.AverageSellingPrice is reported here. Currency conversions on this field use the **DueDate** field's conversion rate.	Money	
FeatureList	Set of **IndependentDemandFeatureList** records that reference this independent demand. Applicable to configurable, made to order end-items (parts where **PartType.FeatureBOMRule** is set to a value other than "Ignore"). The set of string values in this field represents the list of all features required for the final assembly on this order. This feature list is then compared against values in the **BillOfMaterial.FeatureRule** field for each record that defines a component directly used in the end-item assembly that this order is for. If the **FeatureRule** field either matches a value defined in the feature list or is empty, then the component is required for this demand; otherwise, it is not. Thus, this feature ensures that the correct components by feature are selected and dependent demands placed correspondingly throughout the structure. **Note:** This field was modified in Version 2016.2	VectorSet	
FlowToCommon ForecastQuantity	The quantity of this order that consumed forecast. from the common forecast pool (that is, because all of the customer's forecast had already been consumed).	Quantity	

Table 6.148: Calculated IndependentDemand (Mfg) fields

Field name	Description	Data type	Key
Forecast Consumption Date	Reports the date from which the forecast consumption window is based for this demand. Considering the applicable settings in the **ForecastConsumptionDateRule** field on the **DemandStatus** and/or **PartType** tables, this returns the demand's **DueDate**, **RequestDate**, or **Part.PlanningCalendars.Date.FirstDate**. This field is populated for all actual demands (**Order.Type.ProcessingRule** = 'SalesActual') on MPS parts (**Part.Type.ProcessingRule** = 'MPS' or 'MPSConfig'). Otherwise, it returns "Undefined".	Date	
ForecastQuantity	The quantity of this order that consumed forecast. This includes both forecast consumed from the customer's forecast and forecast consumed from the common pool forecast.	Quantity	
GatingConstraint	The Constraint reported for the latest supply allocated to this independent demand from the gating part. Null if that supply's reported Constraint is Null. **Referenced table:** Constraint	Reference	
GatingPart	A reference to the part that determines the AvailableDate for this demand, if it is late. GatingPart is also calculated for Forecast demands (the GatingPart of the latest supply, including spreading). GatingPart for a demand is the GatingPart of the latest available supply allocated to the demand. It will be Null if the demand is satisfied on time. It will be the part itself if the last supply is gated by itself (which includes Constraint, rescheduling limits, time fence), or is available for its ReschedDate, but that is later than the demand due date. **Referenced table:** Part	Reference	
MappedPool	The pool used in netting this demand. The value returned is affected by the **Part.MUEPoolNettingType.PoolRule** setting as follows: • If **PoolRule** is "Net" and the **InputPool** reference on this line item is populated, then that referenced pool is used. • If **PoolRule** is "Net" and the **InputPool** reference is Null, then the pool referenced by **Order.Pool** is used (from the demand order). • If **PoolRule** is "Ignore", "Forecast", or "ForecastOptional", the part's common pool, from the **Part.PlanningCalendars.CommonPool** reference, is always used. • If **PoolRule** is "Optional" and the demand's pool is listed in the corresponding **PoolMap** table (by PartType) or **PoolMapOverride** table (by Part), then the demand's pool is used. Otherwise, the part's common pool is used. **Referenced table:** Pool	Reference	

Table 6.148: Calculated IndependentDemand (Mfg) fields

Field name	Description	Data type	Key
MaterialSpend	The total rolled-up material costs from purchased parts used in satisfying this independent demand. This field summarizes the date-specific cost values reported in the **IndependentDemandCost** table and described on page "IndependentDemandCost table" on page 1073.	Money	
NewProcessCost	Standard labor and overhead cost of planned orders to complete this order. NewProcessCost is calculated as: (UOMConversion (PartSource.LaborCost + PartSource.OverheadCost + PartSource.OverheadCost2) * (inventory) Quantity) from all planned orders pegged back to this IndependentDemand. Currency conversions on this field use the **DueDate** field's conversion rate.	Money	
NewPurchases Cost	The cost of planned order purchase cost attributed to this demand. This is calculated using PartSource.EffUnitCost. Currency conversions on this field use the **DueDate** field's conversion rate.	Money	
OnTimeQuantity	The amount of this demand that can be delivered on time. If Type.ProcessingRule is 'SalesForecast', then the sum of OnTimeQuantity from every Forecast record on this part derived from this record.	Quantity	
PartCustomer	A reference to the entry in the PartCustomer table, if any, that has the same part and customer as this IndependentDemand record. **Referenced table**: PartCustomer	Reference	
PlannedReceipt Date	The date on which the order is currently scheduled to be received at the customer destination (based on the last commitment made to the customer. This is calculated by adding the applicable pick and pack time to **DueDate**, offsetting to the next date on the delivery route's pickup calendar (or the Everyday calendar if a pickup calendar is not defined), and then adding the transit time for the route.	Date	
PlannedShipDate	The date on which the order is currently scheduled to be shipped to the customer destination (based on the last commitment made to the customer). This is calculated by adding the applicable pick and pack time to the **ShipSetAvailableDate** and then offsets to the next date on the delivery route's pickup calendar (or the Everyday calendar if no pickup calendar is specified).	Date	

Table 6.148: Calculated IndependentDemand (Mfg) fields

Field name	Description	Data type	Key
ShipSetAvailable Date	The latest **AvailableDate** reported across all independent demands belonging to the same demand order and ship set. For independent demands not belonging to a ship set, this value is the same as **AvailableDate**.	Date	
TaskNeedDate	The earliest date that this demand is required by any project task associated with it through a **TaskDemandLink** record. If this order is not required by any tasks, then 'undefined' is reported. **Note:** This field belongs to the ProjMgmt namespace.	Date	
ToleranceProfile Zone	A reference to the entry in the ToleranceProfileZone table that applies to this IndependentDemand record. It is used in defining the acceptable levels of change when comparing independent demands against baseline historical demand series. The ToleranceProfile for this record is the value referenced from the PartCustomer field, and the ToleranceProfileZone is set to the entry with the lowest ZoneEndInterval value where `Part.PlanningCalendars.RunDate.FirstDate + ZoneEndInterval ToleranceProfile.ToleranceCalendar > IndependentDemand.DueDate`. **Referenced table**: ToleranceProfileZone	Reference	
Unsatisfied Quantity	The portion of this demand that was left unsatisfied. T This field is intended for use with parts that use partial planning logic. Thus it always returns zero (0) in cases where **Order.Type.PlanningRule** is set to "Full". If **Order.Type.PlanningRule** is set to "Partial", then it represents the portion of the demand that was left unsatisfied because it could not be satisfied within the defined lateness tolerance. Note however that if a demand is left unsatisfied because the part never has any valid part sources or because the part references a **Type.ProcessingRule** of "Ignore", then this field reports a value of zero (0) regardless.	Quantity	
CostInfo	Set of **IndependentDemandCost** records that contain cost values associated with the set of supplies needed to satisfy this demand. Used in calculations that populate the **CostOfGoodsSold** and **MaterialSpend** fields.	Set	
FeatureBOMs	Set of **FeatureBOMForIndependentDemand** records associated with this IndependentDemand.	Set	
FeaturesList	Set of **IndependentDemandFeature** records associated with this IndependentDemand.	Set	
Independent DemandSolutions	Set of **IndependentDemandSolution** records that hold order fulfillment details pertaining to this IndependentDemand.	Set	

Table 6.148: Calculated IndependentDemand (Mfg) fields

Field name	Description	Data type	Key
LateSupplies	Set of **LateSupply** records associated with this IndependentDemand.	Set	
Notes	Descriptive notes appended to this demand. This field can used to enter notes about an independent demand. Each time a note value is added to this field through a worksheet, a new record is created in the IndependentDemand_Notes table with a date and timestamp, user ID, note text, and a reference to the IndependentDemand record against which it was created.	Note	
TaskDemandLinks	Set of TaskDemandLink records associated with this IndependentDemand.	Set	
WhereConsumed ForDemands	Set of WhereConsumedForDemand records associated with this IndependentDemand.	Set	

IndependentDemandFeatureList table

The **IndependentDemandFeatureList** table supports Feature BOM logic and is used to indicate the features required on independent demands for configurable end-items (parts where **PartType.FeatureBOMRule** is set to a value other than "Ignore"). Each record in this table references an **IndependentDemand** record and specifies one feature required by that demand.

Together, all records that reference a given **IndependentDemand** record define the list or set of feature options required by that demand and are represented by the corresponding **IndependentDemand.FeatureList** set field. The set of features are then compared against the **BillOfMaterial.FeatureRule** value for each record that defines a component directly used under the configurable end-item assembly that the demand is for. If the **FeatureRule** value matches a value in the feature list or is empty, then the component is required for the demand (otherwise, it is not).

This table was added in Version 2016.2

Table 6.149: IndependentDemandFeatureList (Mfg) fields

Field name	Description	Data type	Key
Feature	The name of a feature required by the demand referenced on this record. **Note:** Feature names are not case-sensitive, and any leading or trailing spaces in the feature name are ignored. Optionally, the feature name can be enclosed in single or double quotes (but this is not required).	String	Yes
Independent Demand	The end-item demand where the feature specified on this record is required. **Referenced table:** IndependentDemand	Reference (Owning)	Yes

IndependentDemandSolution table

The **IndependentDemandSolution** table supports the Order Fulfillment application available with RapidResponse, and a record is typically added this table by that application when it processes a new **IndependendentDemand** record (customer request).

Each record in this table references a record in the **IndependentDemand** table, and contains additional details for the referenced line item. For example, this table allows for assigning hold codes to demand lines, and also reports the number of customer-requested or supply-driven changes associated with each demand

Note that although use of this table is required by the Order Fulfillment application, none of its fields are used in actual RapidResponse analytic calculations.

Table 6.150: IndependentDemandSolution (Solutions) fields

Field name	Description	Data type	Key
ActualReceipt Date	Used to record the date on which the customer actually received the order (reflects transit time incurred from the point the shipment was made).	Date	
ActualShipDate	Used to record the date on which the order was actually shipped to the customer	Date	
AutoCommit HorizonDate	A date after which the Order Fulfillment application will automatically commit to the customer request. That is, if the line item's **RequestDate** is on or after this date, then the line's **DueDate** is set to the **RequestDate** and the order is automatically promised. Otherwise, manual intervention may be needed in order to commit to the customer request (orders earlier than this date, but after the **FrozenHorizonDate,** will have their **DueDate** set to the **RequestDate** only if there is sufficient unallocated supply). **Note:** This field is calculated when the order is first processed in RapidResponse by adding the **AutoCommitHorizon** field value, from either the **PartCustomer** table (if populated) or else the **PartSolution** table, to the **OrderCreation** date.	Date	
CustomerChange	Indicates whether the order has had a customer requested change (for example, an increase in the order quantity or a change in the requested date). Valid values are: • **N**—the order has not had any customer changes (this is the default). • **Y**—the order has had at least one customer change (this value is automatically set on records when a change is detected).	Boolean	

Table 6.150: IndependentDemandSolution (Solutions) fields

Field name	Description	Data type	Key
DwellTime	Dwell time for this order. This represents extra time, if any, built into the customer request and during which no activity takes place against the order. Calculated as the number of Everyday intervals between **IndependentDemand.RequestDate** and **AutoCommitHorizonDate** at the time the order is first processed in RapidResponse (and not recalculated if the request date subsequently changes). This will be a positive value if the **RequestDate** is later than the **AutoCommitHorizonDate** and 0 (zero) otherwise.	Integer	
EarlyShipWindow	Maximum number of days earlier than the planned ship date that the order is allowed to ship. For example, shipping an order early might allow for early revenue recognition. Shipping the order any earlier than the amount of time specified here requires explicit approval from the customer. This field value should be expressed in terms of the Everyday calendar and is used in calculating the **EarlyShipDate**. If a negative value is specified here, then the default **EarlyShipWindow** from the **Customer** record is used.	Integer	
FrozenHorizon Date	A near-term date before which the Order Fulfillment application will never automatically commit to the customer request. That is, if the order's **RequestDate** is before this date, then the **DueDate** will never be set to that request even if there is supply available to do so. Instead, the **DueDate** is set to the latter of this date or the **AvailableDate**. Manual intervention would then be needed to pull the order back in and commit to a request within the frozen horizon. Note that orders later than this date but before the **AutoCommitHorizonDate** have their **DueDate** set to the request only when there is sufficient unallocated supply available. **Note:** This field is calculated when the order is first processed by adding the **FrozenHorizon** field value, from either the **PartCustomer** table (if populated) or else the **PartSolution** table, to the **OrderCreation** date.	Date	

Table 6.150: IndependentDemandSolution (Solutions) fields

Field name	Description	Data type	Key
HoldCode	The hold code, if any, that has been applied to this line item. Hold codes are used to prevent orders from being processed beyond a particular state (for example, an order might be prevented from shipping due a credit issue or a problem at the customer warehouse). Hold codes can also be specified at the customer-level , and the hold code that applies to a given order line is reported in the **EffectiveHoldCode** field (a hold code at the order line level always takes precedence over one at the customer level). **Referenced table:** HoldCode (Nullable)	Reference	
Independent Demand	The specific line item to which the details on this record apply. **Referenced table:** IndependentDemand	Reference	Yes
LatestDueDate	Used to store the original **DueDate** that the Order Fulfillment application generated on the **IndependentDemand** record. Thus, when exploring options to move demand dates earlier, this date is available for comparison purposes.	Date	
OrderCreation	The date and time at which the order was first imported into RapidResponse.	DateTime	
OrderPromised	Indicates whether a initial date for the order has been committed or promised to the customer. Valid values are: • **N**—a commitment has not yet been made to the customer (default value). • **Y**—a commitment has been made to customer (this value is automatically set when the order is promised in RapidResponse for the first time).	Boolean	
OrderPromised DateTime	The date and time at which a date for the order was committed to the customer.	DateTime	
Processed	Indicates whether the order has been processed. Valid values are: • **N**—Indicates the order is in need of an initial promise date or a re-promising. • **Y**—If this is a new order, indicates an initial commitment has been made to the customer. If this an existing order in need of re-promising, indicates a new commitment has been made to the customer.	Boolean	

IndependentDemandSolution table – calculated and set fields

The following describes the calculated and set fields in the **IndependentDemandSolution** table. For an introduction to this table, and descriptions of its input fields, see "IndependentDemandSolution table" on page 370.

Table 6.151: Calculated IndependentDemandSolution (Solutions) fields

Field name	Description	Data type	Key
CustomerNotes	Notes added to this demand for the purpose of tracking customer-requested changes to orders during the order fulfillment process. Note that this field supports the Order Fulfillment application and should not directly be edited. It is automatically updated whenever a change is made to the request date, quantity, part, or routing on the order. Each time a value is added to this field, a new record is then automatically added to the **IndependentDemandSolution_CustomerNotes** table with a datetime stamp, user ID, note text, and reference to the **IndependentDemandSolution** record against which it was created.	Note	
EarlyShipDate	The earliest date on which this order can ship without requiring explicit approval from the customer. In other words, if the order is ready earlier than the planned ship date, it can potentially ship as early as the date returned by this field. This calculation relies on the **EarlyShipWindow** field (if positive) or else the applicable default **EarlyShipWindow** value from the **Customer** table.	Date	
EffectiveHoldCode	The effective hold code for this line item. If this record has a valid **HoldCode** reference, then it is always reported here. If the **HoldCode** reference is Null, but there is a valid **HoldCode** referenced on the **Customer** record, then that will be reported here. Otherwise, this reference returns Null. **Referenced table:** HoldCode	Reference	

Table 6.151: Calculated IndependentDemandSolution (Solutions) fields

Field name	Description	Data type	Key
ShipSetHasHold Code	Indicates whether a hold code is applied to any line items in the ship set, if any, that this demand belongs to. For example, this can help determine if a hold code on another demand in the same ship set might prevent this one from shipping. Valid values are: • **N**—no demands in the ship set that this one belongs to have hold codes applied. • **Y**—at least one demand in the ship set this one belongs to has a hold code applied.	Boolean	
SupplyNotes	Notes automatically added to this record for the purpose of tracking supply-related changes to demands during the order fulfillment process. This field supports the Order Fulfillment application and should not directly be edited. It is automatically updated whenever a supply-related change is made to the **IndependentDemand** record during the order fulfillment process. Each time a value is added to this field, a new record is automatically added to the **IndependentDemandSolution_ SupplyNotes** table with a datetime stamp, user ID, note text, and reference to the **IndependentDemandSolution** record against which it was created.	Note	

InventoryTransfer table

The **InventoryTransfer** table holds transfers of nettable inventory from one part and site to another. For example, when a customer order is projected to be late due to a supply shortage, one response might be to transfer the required supply from a site with excess on hand inventory to the site that requires it.

Each record in this table contains details of an inventory transfer such as the two parts involved in the transfer (the part with the shortage and the part being transferred), the quantity of inventory being transferred, and the cost and lead time associated with the transfer. Depending on the control settings associated with a given inventory transfer, RapidResponse analytics may decrease the on hand quantity of the transfer part at the sourcing site and create supply for the part at the destination site to reflect the transfer.

Note also that the amount of a given transfer cannot exceed the reported on hand inventory at the site supplying the part. However, care should be taken when using inventory transfers in a backflush environment. For example, when SupplyStatus.State is set to "BackflushButNotAllocated", the dependent requirements of a scheduled receipt are dated at "Past" and the on hand inventory is reduced although the actual OnHand count does not reflect this until the scheduled receipt is built. In this case, an inventory transfer could be created and planned, but the actual supply might not ultimately be available to be moved.

Table 6.152: InventoryTransfer (Mfg) fields

Field name	Description	Data type	Key
ActualDockDate	The actual date the inventory transfer arrived at the receiving dock, which is used in historical reporting. This field is in the **Solutions** namespace. **Note:** This field was added in the Version 2016.2, Service Update 5.	Date	
DockToStock LeadTime	The amount of time required to move supply from the receiving dock to available inventory. It is measured in **Part.PlanningCalendars.TimeUnits**.	Quantity	
ExpiryStartDate	Used to specify the expiry start date for this inventory transfer. If a value is not provided, then the **Date** field from the **OnHand** record used to supply this transfer is used instead (the **EffectiveExpiryStartDate** field reports the actual expiry start date being used for inventory transfers on limiting components). **Default value:** Future	Date	
Id	A unique identifier for this inventory transfer record.	String	Yes
Model	A reference to the model for the **Part**. **Referenced table:** Model	Reference	
Notes	Any notes users have added to this inventory transfer record.	String	
OriginalRecordId	Identifies records that have been sent to your enterprise data sources in a closed-loop operation. This is a concatenation of the date the closed-loop operation was performed and the RecordId value for the record. When data is next updated, this value is compared to the new InventoryTransfer records and ensures the records are not double-counted. The RecordId value is a number representing the sequence a record was created in. Each additional record added to the table increments the RecordId by one, and RecordId values are not reused when records are deleted. For more information about RecordId, see the *RapidResponse Resource Authoring Guide*. This field is in the **Solutions** namespace.	String	
Part	The name of the part (at the destination site) that is receiving the inventory transfer. **Referenced table:** Part **Reference Syntax:** Part.Name, Part.Site	Reference	Yes

Table 6.152: InventoryTransfer (Mfg) fields

Field name	Description	Data type	Key
Pool	A reference to the pool for the Part. **Referenced table:** Pool	Reference	
Quantity	The amount of the inventory transfer. This value is reported in the unit of measure used by the Part.	Quantity	
ShipDate	The date the inventory transfer is expected to leave the sourcing site.	Date	
Source	References the **Source** record that applies to the transfer destination record. **Referenced table**: Mfg::Source (This field is in the Solutions namespace.) **Note:** This field was added in the Version 2016.2, Service Update 5.	Reference	
StartUnit	The start unit for the Part.	Integer	
TransferCost	The total cost of transferring supply from the sourcing site to the destination site.	Money	
TransferModel	A reference to the model for the TransferPart. **Referenced table**: Model	Reference	
TransferPart	The name of the part (at the sourcing site) that is providing the inventory transfer. **Referenced table:** Part **Reference Syntax:** Part.Name, Part.Site	Reference	Yes
TransferPool	A reference to the Pool for the TransferPart. **Referenced table**: Pool	Reference	
TransferStart Unit	The start unit for the TransferPart.	Integer	

Table 6.152: InventoryTransfer (Mfg) fields

Field name	Description	Data type	Key
TransitCalendar	A reference to the calendar in which the **TransitTime** value should be expressed. For example, if the vehicles used to transport goods from the supplying site to the destination site do not operate on weekends, this might be set to a standard Workday calendar. If this reference is left Null, then an Everyday calendar is assumed. **Referenced table:** Core::Calendar (Nullable) **Note:** This table was added in Version 2016.2.	Reference	
TransitTime	The amount of time required to transfer inventory from the sourcing site to the destination site. This value should be expressed in intervals of the **TransitCalendar** (or the Everyday calendar if the **TransitCalendar** reference is left Null)	Quantity	
Type	A control setting that indicates the state of the inventory transfer (received, intransit, not released, or by date) and hence the processing RapidResponse performs on the transfer. **Referenced table**: InventoryTransferType	Reference	

InventoryTransfer table – calculated and set fields

The following describes the calculated and set fields in the **InventoryTransfer** table. For an introduction to this table, and descriptions of its input fields, see "InventoryTransfer table" on page 374.

Table 6.153: Calculated InventoryTransfer (Mfg) calculated fields

Field name	Description	Data type	Key
DockDate	The date the inventory transfer is expected to arrive at the destination site's receiving dock. Calculated as *ShipDate* + *TransitTime*.	Date	
EarliestExpiry Date	Earliest date that on hand inventory can expire if it is to be allotted to this transfer. Determined from the transfer **StockDate** and then offset by the number of expiry calendar intervals specified in **Part.MinimumShelfLife**.	Date	

Table 6.153: Calculated InventoryTransfer (Mfg) calculated fields

Field name	Description	Data type	Key
EffectiveDemand Quantity	The effective demand quantity for this inventory transfer. This value is reported in the TransferPart's unit of measure, and represents the amount to reduce on hand inventory by at the sourcing site. If Type.Status is set to "Received" or "InTransit", this value is always 0. If Type.Status is set to "NotReleased" this value can be between 0 and Quantity (set to Quantity as long as there is sufficient on hand inventory at the sourcing site to satisfy the transfer).	Quantity	
EffectiveExpiry StartDate	The expiry start date for the inventory transfer. Expiry start dates from components are used to determine when expiry date calculations should begin for assemblies with **PartType.ExpiryRule** set to "DependentStart". This field returns the value in **ExpiryStartDate** (if provided) or else set to the **Date** field from the **OnHand** record used to supply the transfer. Note that if the part is not a limiting component (has **ExpiryType.ProcessingRule** of "Normal"), then this field reports a value of "Future".	Date	
EffectiveSupply Quantity	The effective supply quantity for this inventory transfer. This value is reported in the Part's unit of measure, and represents the amount of supply to create at the destination site. If Type.Status is set to "Received", this value is always 0. If Type.Status is set to either "InTransit" or "NotReleased", this value can be between 0 and Quantity (set to Quantity as long as there is sufficient on hand inventory at the sourcing site to satisfy the transfer).	Quantity	
EffectiveUnit TransferCost	The per unit cost of this inventory transfer. Calculated as *TransferCost /EffectiveSupplyQuantity*. Currency conversions on this field use the **ShipDate** field's conversion rate.	Money	
ExpiryDate	The date on which this inventory transfer expires (is no longer usable). It is set to the expiry date of the OnHand record supplying the transfer.	Date	
ExpiringQuantity	The amount of the inventory transfer that will not be used before its expiry date.	Date	
StockDate	The date the inventory transfer is expected to be received into inventory at the destination site. Calculated as *ShipDate* + *TransitTime* + *DockToStockLeadTime* (adjusted by Part.PlanningCalendars.TimeUnits).	Date	

ItemSource table

The **ItemSource** table defines multiple sources of supply (**ItemSource** records) for parts (**PartSource** records) that have similar deviations in their planning parameters, such as lead time.

The lead time deviation is determined based on the difference between the **PartSource**'s fixed lead time and the **PartSource**'s actual lead time from the **HistoricalSupplyActual** data, as reported by **ItemSourcePartSourceHistoricalLeadTime**.

Yield deviation is determined based on the difference between the **PartSource**'s yield and the actual yield from the **HistoricalReceipt** data, as reported by **ItemSourcePartSourceHistoricalReceipt**.

This table was added in Version 2016.2, Service Update 21.

Table 6.154: ItemSource (Mfg) fields

Field name	Description	Data type	Key
Id	A key to allow item sources with the same Part and Source combination to have various combinations of BOMAlternate and Routing settings.	String	Yes
AcceptLeadTimeChanges	Used to manually accept the projected lead times for the **ItemSource**. Valid values are: • **Y** • **N** **Default value:** N	Boolean	
AcceptYieldChanges	Used to manually accept the projected yields for the **ItemSource**. Valid values are: • **Y** • **N** **Default value:** N	Boolean	
AutomatedLeadTimeType	The **AutomatedLeadTimeType** that defines how the projected lead times are processed for the **ItemSource**. **Referenced table:** AutomatedLeadTimeType (Nullable) **Reference syntax:** AutomatedLeadTimeType.Value	Reference	
AutomatedYieldType	The **AutomatedYieldType** that defines how the projected yields are processed for the **ItemSource**. **Referenced table:**AutomatedYieldType (Nullable) **Reference syntax:** AutomatedYieldType.Value	Reference	
BOMAlternate	A reference to the alternate BOM for the **ItemSource**. **Referenced table:**BOMAlternate (Nullable) **Reference syntax:** BOMAlternate.Value	Reference	

Table 6.154: ItemSource (Mfg) fields

Field name	Description	Data type	Key
Cluster	A reference to the **Cluster** for the **ItemSource**. **Referenced table:** Cluster (Nullable) **Reference syntax:** Cluster.Name	Reference	
HistoricalSupplyCategoryRule	Determines whether the **ItemSourceHistoricalSupplyCategory** is to be interpreted as the set of **HistoricalSupplyCategory** records to include or exclude when matching **HistoricalSupplyActual** records for **ItemSourcePartSourceHistoricalLeadTime**. Valid values are: • **Include** —Any category in **ItemSourceHistoricalSupplyCatergory** will be used by the Machine Learning service. Note that this value is currently unsupported. • **Exclude**— Any category in **ItemSourceHistoricalSupplyCatergory** will be ignored by the Machine Learning service. Note that only this value is currently supported. **Default value:** Exclude **Note:** This field was added in Version 2016.2, Service Update 23 and is hidden.	Enum	
LeadTimeCorrectionStatus	Specifies whether the projected lead times for the **ItemSource** have been reviewed. Valid values are: • **Not Reviewed** —The projected lead times have not been reviewed and not yet copied to the planning data (**TimePhasedPartSourceLeadTime**) for the associated **PartSource** records. • **Reviewed** —The projected lead times have been reviewed and copied to the planning data (**TimePhasedPartSourceLeadTime**) for the associated **PartSource** records. **Default value:** Not Reviewed	Enum	
Part	A reference to the **Part** associated with the **ItemSource**. **Referenced table:** Part **Reference syntax:** Part.Name, Part.Site	Reference	Yes
Routing	A reference to the sequence of operations (**Routing**) associated with the **ItemSource**. **Referenced table:**Routing **Reference syntax:** Routing.Id, Routing.Site	Reference	

Table 6.154: ItemSource (Mfg) fields

Field name	Description	Data type	Key
Source	A reference to the **Source** associated with the **ItemSource**. **Referenced table:** Source **Reference syntax:** Source.DestinationSite, Source.ID, Source.Supplier	Reference	Yes
YieldCluster	A reference to the **Cluster** associated with the **ItemSource** for yields. **Referenced table:**Cluster (Nullable) **Reference syntax:** Cluster.Name, Cluster.SelfHealingParameter	Reference	
YieldCorrectionStatus	Specifies whether or not the given **ItemSource** has been reviewed for yield correction or not. Valid values are: • **Reviewed** • **NotReviewed** **Default value:** NotReviewed	Enum	

ItemSource table – calculated and set fields

The following describes the calculated and set fields in the **ItemSource** table.

Table 6.155: ItemSource calculated (Mfg) fields

Field name	Description	Data type	Key
CalcHistoricalLeadTimeError	A measure (e.g. mean absolute deviation) of the error between the posted lead times (from **PartSource.FixedLeadTime** or **TimePhasedPartSourceLeadTime.FixedLeadTime**) and the actual lead times (from **HistoricalSupplyActual.LeadTime**). This measure determines how accurate the posted lead times have been and is used to determine whether an **ItemSource** is near, inside, or outside tolerance. The particular error measure used to calculate this value is determined by the value of **AutomatedLeadTimeType.HistoricalLeadTimeErrorMeasure**. The input to this calculation may be seen in the **ItemSourcePartSourceHistoricalLeadTime** table. For a given **ItemSource**, the value of this field is the mean absolute deviation (or mean absolute percentage error) between **ItemSourcePartSourceHistoricalLeadTime.PartSourceLeadTime** and **ActualLeadTime** for all records. **Note:** This calculation is not based on a limited time horizon. It uses all matching **HistoricalSupplyActual** records for which there is an effective **PartSource**. **Note:** If no error measure can be calculated (i.e. if there are no matching **HistoricalSupplyActual** records and effective **PartSource** records can be found), then the value of this field is -1.	Quantity	

Table 6.155: ItemSource calculated (Mfg) fields

Field name	Description	Data type	Key
CalcHistoricalYieldError	A measure (e.g. mean absolute deviation) of the error between modeled yields (from **PartSource.Yield** or **TimePhasedYield**) and the actual yield (from **HistoricalReceipt.ReceivedQuantity**). This measure determines how accurate the posted yields have been and is used to determine whether an **ItemSource** is near, inside, or outside tolerance. The particular error measure used to calculate this value is determined by the value of **AutomatedYieldType.HistoricalYieldErrorMeasure**. The input to this calculation may be seen in the **ItemSourcePartSourceHistoricalReceipt** table. For a given **ItemSource**, the value of this field is the error measure between **ItemSourcePartSourceHistoricalReceipt.AdjustedPartSourceYield** and **ItemSourcePartSourceHistoricalReceipt.EffectiveHistoricalYield** for all records. **Note:** This calculation is not based on a limited time horizon. It uses all matching **HistoricalReceipt** records for which there is an effective **PartSource**. **Note:** If no error measure can be calculated (i.e. if there are no matching **HistoricalReceipt** records and effective **PartSource** records can be found), then the value of this field is -1.	Quantity	
CalcLeadTimeZone	The zone into which the lead time deviation for the **ItemSource** falls. For example, if 0 ≤ **NearToleranceThreshold** ≤ **OutsideToleranceThreshold**, then this field's value is equivalent to: • **None** —If **AutomatedLeadTimeType** = Null or **AutomatedLeadTimeType.ProcessingRule** = Ignore. • **Inside** —If **CalcHistoricalLeadTimeError** < **NearToleranceThreshold** . • **Near** —If **NearToleranceThreshold** ≤ **CalcHistoricalLeadTimeError** < **OutsideToleranceThreshold**. • **Outside** —If **OutsideToleranceThreshold** ≤ **CalcHistoricalLeadTimeError**. The value for this field is used in the calculation for **CalcUseLeadTimeChanges**.	Enum	

Table 6.155: ItemSource calculated (Mfg) fields

Field name	Description	Data type	Key
CalcProjectedLeadTimeCOV	The coefficient of variation of **ProjectedLeadTimes.FixedLeadTime** for this **ItemSource**. The coefficient of variation is defined as standard deviation divided by mean. **Note:** If the mean lead time is 0, then this field reports -1.	Quantity	
CalcProjectedYieldCOV	The coefficient of variation of **ProjectedYields.Yield** for this **ItemSource**. **Note:** If the mean projected yield is 0, then this field reports -1.	Quantity	
CalcUseLeadTimeChanges	Whether the values recommended in the **ProjectedLeadTime** table should be applied, either because they should be accepted automatically or because the user has accepted them manually. This field's value is equal to 'Y' when: • **CalcLeadTimeZone** ≠ None and **AcceptLeadTimeChanges** = Y, or • **CalcLeadTimeZone** = Inside and **InsideToleranceAction** = AutoAccept, or • **CalcLeadTimeZone** = Near and **NearToleranceAction** = AutoAccept, or • **CalcLeadTimeZone** = Outside and **NearToleranceAction** = AutoAccept.	Boolean	

Table 6.155: ItemSource calculated (Mfg) fields

Field name	Description	Data type	Key
CalcYieldZone	The zone (inside, near or outside tolerance) into which this ItemSource falls. If **AutomatedYieldType** = Null or **AutomatedYieldType.ProcessingRule**= Ignore or **CalcYieldUsageRule** = Ignore or **AutomatedYieldType.NearToleranceThreshold** > **AutomatedYieldType.OutsideToleranceThreshold**, or the **SelfHealingSupplyChain** license is not enabled, or the **CalcHistoricalYieldError** is < 0, then this field's value is None. Otherwise, assuming that 0 ≤ **AutomatedYieldType.NearToleranceThreshold** ≤ **AutomatedYieldType.OutsideToleranceThreshold**. Then, this field's value is: • Inside, if **CalcHistoricalYieldError** < **AutomatedYieldType.NearToleranceThreshold** • Near, if **AutomatedYieldType.NearToleranceThreshold** ≤ **CalcHistoricalYieldError** < **AutomatedYieldType.OutsideToleranceThreshold** • Outside, if **AutomatedYieldType.OutsideToleranceThreshold** ≤ **CalcHistoricalYieldError**	Boolean	
CalcUseYieldChanges	Whether the values recommended in the **ProjectedYield** table should be applied, either because they should be accepted automatically or because the user has accepted them manually. This field's value is equal to 'Y' when: • **CalcYieldZone** ≠ None and **AcceptYieldChanges** = Y, or • **CalcYieldZone** = Inside and **InsideToleranceAction** = AutoAccept, or • **CalcYieldZone** = Near and **NearToleranceAction** = AutoAccept, or • **CalcYieldZone** = Outside and **OutsideToleranceAction** = AutoAccept.	Boolean	
CalcYieldUsageRule	YieldUsage rule applicable to the **ItemSource**, calculated based on the **OrderPolicy.YieldUsage** value for all relevant **PartSources**. If an **OrderPolicy.YieldUsage** value is Ignore, the PartSource is considered to be invalid.	Boolean	

Table 6.155: ItemSource calculated (Mfg) fields

Field name	Description	Data type	Key
ItemSourceEffectivePartSources	A set of calculated **ItemSourceIntervalEffectivePartSource** records associated with this **ItemSource**. **Referenced table:** "ItemSourceIntervalEffectivePartSource table" on page 1088	Set	
ItemSourcePartSourceEffectivityIntervals	A set of calculated **ItemSourcePartSourceEffectivityInterval** records associated with this **ItemSource**. **Referenced table:** "ItemSourcePartSourceEffectivityInterval table" on page 1089	Set	
ItemSourcePartSourceHistoricalLeadTimes	A set of calculated **ItemSourcePartSourceHistoricalLeadTime** records associated with this **ItemSource**. **Referenced table:** "ItemSourcePartSourceHistoricalLeadTime table" on page 1089	Set	
ProjectedLeadTimes	A set of **ProjectedLeadTime** records associated with this **ItemSource**. **Referenced table:** "ProjectedLeadTime table" on page 505	Set	
ProjectedYields	A set of **ProjectedYield** records associated with this **ItemSource**. **Referenced table:** "ProjectedYield table" on page 506	Set	

ItemSourceFitOutput table

The ItemSourceFitOutput table supports the Self-Healing Supply Chain in RapidResponse.

This table shows the result of fitting the statistical model for forecast items in the Self-Healing Supply Chain process, such as lead time. This table contains output parameters associated with a particular forecast model along with details generated from fitting the model such as model constants and error measures.

Table 6.156: ItemSourceFitOutput (Mfg) fields

Field name	Description	Data type	Key
ItemSource	The ItemSource record associated with the current record.	Reference	Yes
ValueName	The name of the metric or characteristic being reported. For example, MeanAbsolutePercentageError (MAPE), which is the mean average percentage error calculated from the difference between the historically observed lead time or yields and the defined lead time or yields for each series. Reference to the "ItemSourceFitOutputValueName table" on page 388.	Reference	Yes
SelfHealingParameter	Indicates the Self-Healing use case where the information in the record is applicable (for example, LeadTime).	String (Enum)	Yes
AsOfDate	Date when the current record was generated or inserted.	Date	
ForecastModel	The forecast model used to generate this fitted output. Reference to the "ItemSourceFitOutputForecastModel table" on page 388.	Reference	
Class	The type of output parameter being reported in this record. For example, ErrorMeasure, to represent an error measure of fitted values against the input data points. Reference to the "ItemSourceFitOutputClass table" on page 387.	Reference	
ValueQuantity	Quantity associated with the metric. Only applicable if ValueType is Quantity.	Quantity	
ValueText	Text associated with the metric. Only applicable if ValueType is Text.	String	
ValueDate	Date associated with the metric. Only applicable if ValueType is Date.	Date	

ItemSourceFitOutputClass table

This table allows customers to define a custom class to use for forecast reporting by the Self-Healing Supply Chain. The class is defined at deployment time, and is referenced by the "ItemSourceFitOutput table" on page 386.

The ItemSourceFitOutputClass table supports the Self-Healing Supply Chain in RapidResponse.

Table 6.157: ItemSourceFitOutputClass (Mfg) fields

Field name	Description	Data type	Key
Value	The class of the record. For example, ErrorMeasure.	String	Yes
Description	An optional description of the referenced class. This value is not used by the Self-Healing Supply Chain.	String	

ItemSourceFitOutputForecastModel table

This table allows customers to have a custom forecast model used by the Self-Healing Supply Chain. The forecast model is defined at deployment time, and is referenced by the "ItemSourceFitOutput table" on page 386.

The ItemSourceFitOutputForecastModel table supports the Self-Healing Supply Chain in RapidResponse.

Table 6.158: ItemSourceFitOutputForecastModel (Mfg) fields

Field name	Description	Data type	Key
Value	The name of the forecast model to use.	String	Yes
Description	An optional description of the referenced value. This value is not used by the Self-Healing Supply Chain.	String	

ItemSourceFitOutputValueName table

This table allows customers to have a custom metric reported by the Self-Healing Supply Chain. The metric is defined at deployment time, and is referenced by the "ItemSourceFitOutput table" on page 386.

The ItemSourceFitOutputValueName table supports the Self-Healing Supply Chain in RapidResponse.

Table 6.159: ItemSourceFitOutputName (Mfg) fields

Field name	Description	Data type	Key
Value	The name of the metric or characteristic reported.	String	Yes
Description	An optional description of the referenced value. This value is not used by the Self-Healing Supply Chain.	String	

ItemSourceHistoricalSupplyCategory table

The **ItemSourceHistoricalSupplyCategory** table defines a set of **HistoricalSupplyCategory** records that are associated with an **ItemSource**. By default, **HistoricalSupplyActual** records from all **HistoricalSupplyCategory**s will be used by the Machine Learning service except those that are added in this table. The **ItemSourcePartSourceHistoricalLeadTime** calculated table will be filtered to exclude the **HistoricalSupplyActual** data for the **HistoricalSupplyCategory** records that are added in this table.

The **HistoricalSupplyActual** data is required as input to calculate the **ItemSourcePartSourceHistoricalLeadTime**.

This table was added in Version 2016.2, Service Update 23 and replaces the **ItemSource**.**HistoricalSupplyCategory** field.

Table 6.160: ItemSourceHistoricalSupplyCategory (Mfg) fields

Field name	Description	Data type	Key
HistoricalSupplyCategory	Defines the **HistoricalSupplyCategory** records to exclude from the historical supply data that will be sent to the Machine Learning server. Any records that are added will be ignored. If there are no records in the **ItemSourceHistoricalSupplyCategory** table, then all historical supply categories will be included and analyzed by the Machine Learning server. **Referenced table:** "HistoricalSupplyCategory table" on page 350	Reference	Yes

Job table

The **Job** table logs the status of the machine learning jobs used to calculate the **ProjectedLeadTime** and **ProjectedYield**, the **Cluster** and the **ClusterProperty** for the **ItemSource** that is configured for the Self-Healing Supply Chain.

This table was added in Version 2016.2, Service Update 21 and is unversioned.

Notes:

- This table is imported into the MLService namespace during the installation of the Self-Healing Supply Chain.
- The status of the machine learning jobs for the Self-Healing Supply Chain can be monitored with the **Job Status** worksheet in the **Self-Healing Job Status** workbook. The **Job Status** worksheet reports the status of the GetPrepData, Forecast, and Cluster jobs.

Table 6.161: Job (MLService) fields

Field name	Description	Data type	Key
Description	The job description. For example: "Forecasting is in progress".	String	
Id	The job Id created by the Machine Learning service.	String	
Name	The job name. The jobs are: • **GetPrepData** —Retrieves **HistoricalSupplyActual** and **HistoricalReceipt**data from **ItemSourcePartSourceHistoricalLeadTime** and **ItemSourcePartSourceHistoricalReceipt**. • **Forecast** —Performs the calculations for **ProjectedLeadTime** and **ProjectedYield**. • **Cluster** —Performs the calculations for **Cluster** and **ClusterProperty**.	String	
Status	The job status. The job statuses are: • **Started** • **In Progress** • **No Data** • **Completed** • **Failed** **Note:** After data cleansing, if there is no data for Forecast and Cluster, GetPrepData will first send a "No Data" status and then send a "Job Complete" status.	String	
Timestamp	The current timestamp in UTC format.	DateTime	
Type	The job type (User, Operational, etc.).	String	
UseCase	The use case for this job.	String	

KPI table

The KPI table identifies each unique key performance indicator in RapidResponse. Records in this table are referenced on values loaded into the HistoricalPartKPI table as discussed in "HistoricalPartKPI table" on page 343.

Table 6.162: KPI (Mfg) fields

Field name	Description	Data type	Key
Description	A description of this key performance indicator.	String	
EnableUOM	Specifies whether this key performance indicator (KPI) has a unit associated with it and can be converted to other unit of measures. This field is not used by used by RapidResponse analytics and is intended to support writing certain worksheet column expressions. For example, it might be referenced in a conditional expression that determines whether a value in the **HistoricalPartKPI** table should have a unit of measure conversion applied or returned in its raw stored value. Valid values are: • **N**—the KPI does not have a unit/can't be converted. • **Y**—the KPI has a unit/can be converted.. **Default value**: N **Note**: This field was added in Version 2016.2, Service Update 30.	Boolean	
Value	A unique identifier for this key performance indicator.	String	Yes

Location table

The **Location** table identifies an inventory location within a warehouse.

Table 6.163: Location (Mfg) fields

Field name	Description	Data type	Key
Id	An identification code for the location within the warehouse (for example, stock room). **Default value**: blank string	String	Yes
Name	The name of the location. **Default value:** blank string	String	
StorageType	A reference to the storage type that is associated with this location. This field is in the **Solutions** namespace. **Referenced table**: Solutions::StorageType **Note:** This field was added in Version 2016.2, Service Update 5.	Reference	
Warehouse	The warehouse where this location is. **Referenced table:** Warehouse **Reference Syntax:** Warehouse.Id, Warehouse.Site	Reference	Yes

Location table – calculated and set fields

The following describes the calculated and set fields in the Location table. For an introduction to this table, and descriptions of its input fields, see "Location table" on page 391.

Table 6.164: Calculated Location (Mfg) fields

Field name	Description	Data type	Key
OnHands	Set of OnHand records for this location.	Set	

LogisticsLocation table

This table identifies locations used for cross-docking, including airports, customs, ports, and other logistics locations. It supports mapping capabilities in RapidResponse.

This table was added in Version 2016.2, Service Update 9.

Table 6.165: LogisticsLocation (Mfg) fields

Name	Description	Data type	Key
Address	The street address of the logistics location. If this table is used to support maps, the address in this field determines the geocode that is used to mark the location on the map. To ensure that the correct geocode is used, follow the guidelines outlined in "Using address data to support maps" on page 1735.	String	
Description	A description of this logistics location.	String	
Email	Email address of the contact person for this logistics location.	String	
Id	A unique identifier for this logistics location.	String	Yes
Phone	The phone number of the contact person for this logistics location.	String	
ProcessingTime	Processing time at this location. This field is included for informational purposes. The units (eg. hours or days) are not specified in RapidResponse.	Quantity	

Table 6.165: LogisticsLocation (Mfg) fields

Name	Description	Data type	Key
Type	Type of logistics location. Valid values are: • Airport • Customs • Logistics • Port **Default value:** Logistics	String (Enum)	

LogisticsLocation table – calculated and set fields

The following describes the calculated and set fields in the LogisticsLocation table. For an introduction to this table, and descriptions of its input fields, see "LogisticsLocation table" on page 392.

Table 6.166: LogisticsLocation (Mfg) calculated fields

Name	Description	Data Type	Key
Airports	Set of Shipment records for which this LogisticsLocation is referenced in the Airport field.	Set	
Customss	Set of Shipment records for which this LogisticsLocation is referenced in the Customs field.	Set	
LogisticsLocations	Set of Carrier records for which this LogisticsLocation is referenced in the LogisticsLocation field.	Set	
Ports	Set of Shipment records for which this LogisticsLocation is referenced in the Ports field.	Set	

MEIOLeadTime table

The **MEIOLeadTime** table identifies each part for which variable lead time parameters should be generated for use in multi-echelon safety stock calculations (assuming the part belongs to a multi-echelon family).

Each record in this table is identified by its **PartSource** reference and also references a control table record that determines how parameters such as average lead time and standard deviation of lead time are calculated. Additionally, this table contains input fields that can be used to manually provide certain lead time parameters rather than having them calculated based on historical data.

Note: All MEIO calculations are expressed in Everyday calendar.

Table 6.167: MEIOLeadTime (Mfg) fields

Field name	Description	Data type	Key
Average	The known or estimated average of the part's historical lead time values. Typically used when there is insufficient historical supply data available to calculate the parameter. This field is only applicable when **Type.ProbabilityDistribution** is set to "Normal" and **Type.StandardDeviationRule** is set to either "Manual" or "CoefficientOfVariation". **Note:** This field is expressed in Everyday calendar.	Quantity	
Distribution Profile	A reference to a distribution profile containing discrete lead time values along with the probability associated with each. This field is only applicable when **Type.ProbabilityDistribution** is set to "Discrete". **Referenced table:** MEIOLeadTimeDistribution (Nullable)	Reference	
LeadTimeOutlier MovingAverage Window	The length of the moving average window for historical lead time. For more information, see the **SafetyStockItem.LeadTimeOutlierMovingAverageWindow** field. **Default value**: 3 **Note:** This field was added in Version 2016.2, Service Update 5.	Quantity	
LeadTimeOutlier Threshold	The threshold for detecting outliers in historical lead time. For more information, see the **SafetyStockItem.LeadTimeOutlierThreshold** field. **Default value**: 3 **Note:** This field was added in Version 2016.2, Service Update 5.	Quantity	
LeadTimeOutlier Type	A reference to the **OutlierType** that defines how to process outliers in historical lead time. To be reported in **MEIOHistoricalSupply**. **Default value**: Null **Referenced table**: OutlierType (Nullable) **Note:** This field was added in Version 2016.2, Service Update 5.	Reference	

Table 6.167: MEIOLeadTime (Mfg) fields

Field name	Description	Data type	Key
LeadTimeSmoothingAfterIntervalCount	When smoothing historical lead time outliers for safety stock items, this indicates the default number of **Type.IntervalsCalendar** periods forward over which to spread the values. This occurs after any backward spreading. For more information, see the **SafetyStockItem.LeadTimeSmoothingAfterIntervalCount** field. **Note:** This field was added in Version 2016.2, Service Update 5.		
LeadTimeSmoothinBeforeIntervalCount	When smoothing historical lead time outliers for safety stock items, this indicates the default number of **Type.IntervalsCalendar** periods backward over which to spread the values. This occurs after any forward spreading. For more information, see the **SafetyStockItem.LeadTimeSmoothingBeforeIntervalCount** field. **Note:** This field was added in Version 2016.2, Service Update 5.		
PartSource	A reference to a part and source whose historical supplies should be used in calculating lead time parameters. A given historical supply for a part can be used in determining lead time parameters if the **HistoricalSupplyActual.Source** value matches the source returned by this reference. If a part in a multi-echelon family has multiple sources of supply, then one record should be added to this table for each effective part source that has variable/random lead time. **Referenced table:** PartSource	Reference	Yes
Standard Deviation	The known or estimated standard deviation of the part's historical lead time values. Typically used when there is insufficient historical supply data available to calculate the parameter. This field is only applicable when **Type.ProbabilityDistribution** is set to "Normal" and **Type.StandardDeviationRule** is set to either "Manual" or "CoefficientOfVariation". **Note:** This field is expressed in Everyday calendar.	Quantity	

Table 6.167: MEIOLeadTime (Mfg) fields

Field name	Description	Data type	Key
Type	A reference to the control setting that determines how lead time parameters are calculated and used for this part. For example, do its historical lead times follow a normal or discrete distribution. **Referenced table:** MEIOLeadTimeType	Reference	

MEIOLeadTime table – calculated and set fields

The following describes the calculated and set fields in the **MEIOLeadTime** table. For an introduction to this table, and descriptions of its input fields, see "MEIOLeadTime table" on page 393.

Table 6.168: Calculated MEIOLeadTime (Mfg) fields

Field name	Description	Data type	Key
CalcAverage	Average lead time for this part source as calculated based on all applicable input and control settings.	Quantity	
CalcStandard Deviation	Standard deviation of lead time for this part source as calculated based on all applicable input and control settings.	Quantity	
Historical Supplies	Set of historical supplies reported in the **MEIOHistoricalSupply** table that reference this record through the **Item** reference.	Set	

MEIOLeadTimeDistributionProfile table

The **MEIOLeadTimeDistributionProfile** table contains named lead time distribution profiles that can be used for parts in multi-echelon safety stock families.

These profiles are used in calculating the average and standard deviation of lead time values for items where lead time is modelled as having a discrete distribution (that is, **MEIOLeadTimeType.ProbabilityDistribution** is set to "Discrete"). The points that make up each profile consist of a lead time value and weight and are stored in records in the **MEIOLeadTimeDistributionProfilePoint** table.

Table 6.169: MEIOLeadTimeDistributionProfile (Mfg) fields

Field name	Description	Data type	Key
Description	A description of this lead time distribution profile.	String	
Name	A unique name that identifies this lead time distribution profile.	String	Yes

MEIOLeadTimeDistributionProfile table – calculated and set fields

The following describes the calculated and set fields in the **MEIOLeadTimeDistributionProfile** table. For an introduction to this table, and descriptions of its input fields, see "MEIOLeadTimeDistributionProfile table" on page 396.

Table 6.170: Calculated MEIOLeadTimeDistributionProfile (Mfg) fields

Field name	Description	Data type	Key
MEIOLeadTimes	Set of MEIOLeadTime records containing lead time parameters that use this profile.	Set	
Points	Set of MEIOLeadTimeDistributionProfilePoint records containing the discrete lead time points that belong to this profile.	Set	

MEIOLeadTimeDistributionProfilePoint table

The **MEIOLeadTimeDistributionProfilePoint** table contains the discrete point values that make up a given lead time distribution profile (as defined in the referenced **MEIOLeadTimeDistributionProfile** table). Each record in this table specifies a lead time value along with a weight to assign to that value within its distribution profile.

For example, if the discrete lead times associated with a given profile is expected to be seven days for fifty-percent of the time, ten days for thirty-percent of the time, and fifteen days for twenty-percent of the time, then records similar to the following might be added:

Profile	Value	Weight
Profile1	7	5
Profile1	10	3
Profile1	15	2

Table 6.171: MEIOLeadTimeDistributionProfilePoint (Mfg) fields

Field name	Description	Data type	Key
Id	A unique string identifier for this profile point.	String	Yes
Profile	A reference to the named lead time profile this point belongs to. **Referenced table:** MEIOLeadTimeDistributionProfile	Reference	Yes
Value	The lead time value associated with this profile point. This value should be expressed as either a number of days or as a multiplier used to determine lead time from the calculated average lead time (based on the **DistributionProfilePoint** setting on the applicable **MEIOLeadTimeType** record).	Quantity	
Weight	The weight to assign to this point value in the referenced distribution profile. The probability assigned to this point value is then determined by dividing this weight by the sum of all weights in the profile.	Quantity	

MEIOLeadTimeOutlier table

This table stores outlier adjustments for historical data associated with a MEIO stage. It is similar to **SafetyStockItemOutlier**, except this table references **MEIOLeadTime** instead of **SafetyStockItem**.

- Outliers are calculated based on the **MEIOLeadTime** table and the results are stored in the **MEIOLeadTimeOutlierResult** and the **MEIOLeadTimeOutlierResultSummary** tables.
- The LeadTime in **MEIOHistoricalSupply** will be corrected based on the data in this table.

This table was added in Version 2016.2, Service Update 5 to support the **Inventory Planning and Optimization** application.

Field name	Description	Data type	Key
Adjustment	The quantity of the outlier adjustment. This can be negative value.	Quantity	
Date	The actual date associated with the historical supply record. For example, this might represent the date parts shipped from the dock. **Note:** Corresponds to **MEIOHistoricalSupply.Date**	Date	Yes
MEIOLeadTime	A reference to the **MEIOLeadTime** to which the outlier adjustment applies. **Referenced table**: MEIOLeadTime	Reference	Yes

Field name	Description	Data type	Key
Notes	Descriptive notes appended to this record.	Notes	
UseWhen Detecting Outliers	Specifies whether to apply or ignore the **SafetyStockItem** record before detecting outliers when calculating **MEIOLeadTimeOutlierResult**. Valid values are: • **Y**—The historical data series for the **SafetyStockItem** record is used to detect outliers. • **N**—The historical data series for the **SafetyStockItem** record is not used to detect outliers. **Default value**: Y **Note:** This field has the same functionality as **ForecastItemParametersOutlier.ProcessingRule** = "All".	Boolean	

Metric table

The **Metric** table stores metric definitions for metrics used in live lenses and comparison scorecards.

This table was added in Version 2016.2, Service Update 19.

Table 6.172: Metric (Solutions) fields

Field name	Description	Data type	Key
Metric	The name of the metric.	String	Yes
ValueType	The type of metric: Quantity or Money.	String (Enum)	

Metric table – calculated and set fields

The following describes the calculated and set fields in the Metric table. For an introduction to this table, and descriptions of its input fields, see "Metric table" on page 399.

Table 6.173: Metric (Solutions) fields

Field name	Description	Data type	Key
ConstraintMetrics	The set of constraint and metric definition combinations that belong to this metric definition. **Referenced table:** PartMetric	Set	
PartMetrics	The set of part and metric definition combinations that belong to this metric definition. **Referenced table:** PartMetric	Set	
SiteMetrics	The set of site and metric definition combinations that belong to this metric definition. **Referenced table:** SiteMetric	Set	

MetricAsOf table

The **MetricAsOf** table stores the date that the metric calculations are generated on for the PartMetric, SiteMetric, and ConstraintMetric tables.

This table was added in Version 2016.2, Service Update 19.

Table 6.174: MetricAsOf(Solutions) fields

Field name	Description	Data type	Key
Date	The date that metric calculations are generated.	Date	Yes

MetricAsOf table – calculated and set fields

The following describes the calculated and set fields in the MetricAsOf table. For an introduction to this table, and descriptions of its input fields, see "MetricAsOf table" on page 400.

Table 6.175: MetricAsOf (Solutions) fields

Field name	Description	Data type	Key
ConstraintMetrics	The set of constraint and metric definition combinations that belong to the stored metric calculations. **Referenced table:** ConstraintMetric	Set	
PartMetrics	The set of part and metric definition combinations that belong to the stored metric calculations. **Referenced table:** PartMetric	Set	

Table 6.175: MetricAsOf (Solutions) fields

Field name	Description	Data type	Key
SiteMetrics	The set of site and metric definition combinations that belong to the stored metric calculations. **Referenced table:** SiteMetric	Set	

Model table

A model represents a variant of a part. A model uses the same part number, but is different from other models of the same part. In classic APICS terms, there should be a different part number for each model or part combination. However, primarily to simplify bill of material maintenance, the RapidResponse data model uses a single part number. Supply of one model cannot be used to satisfy demand for a different model.

This table is only available for use if you have enabled Model-Unit Effectivity.

The **Model** table supports the Model and Unit-Effectivity analytics. It contains the names of every model used by any part.

The default value in the **Model** table of 'None' (and the only model entry for RapidResponse if Model-Unit Effectivity has not been enabled) is special and indicates that this is not really a model. For example, when a part is not netted by model (for example, the value of Part.MuePoolNettingType.ModelRule is 'Ignore'), all supplies and demands for the part are set to use the Default value and therefore not really treated as models.

Table 6.176: Model (Mfg) fields

Field name	Description	Data type	Key
Description	Additional information about the model. **Default value**: blank string	String	
Value	The name of a model. Note that the same model name can be applied to different parts, and may have different meanings for each part with which it is used. **Default value**: None **Note:** The first model name loaded into this table is called None. This is the default model.	String	Yes

Model table – calculated and set fields

The following describes the calculated and set fields in the Model table. For an introduction to this table, and descriptions of its input fields, see "Model table " on page 401.

Table 6.177: Calculated Model (Mfg) fields

Field name	Description	Data type	Key
Allocations	Set of Allocation records associated with this model.	Set	
Baseline PlannedOrders	Set of BaselinePlannedOrder records associated with this model.	Set	
BillOfMaterials	Set of BillOfMaterial records associated with this model.	Set	
BOMTypes FlowedFrom	Set of BOMType records associated with this model.	Set	
CRPOperations	Set of CRPOperation records associated with this model.	Set	
Independent Demand	Set of IndependentDemand records associated with this model.	Set	
Inventory Transfers	Set of InventoryTransfer records associated with this model (through the Model reference).	Set	
Inventory TransferModels	Set of InventoryTransfer records associated with this model (through the TransferModel reference).	Set	
OnHands	Set of OnHand records associated with this model.	Set	
Operations	Set of Operation records associated with this model.	Set	
Scheduled Receipts	Set of ScheduledReceipt records associated with this model.	Set	
Supply Allocations	Set of SupplyAllocation records associated with this model.	Set	

Notification table

The Notification table defines the information related to notifications for process instances and activities. Each record in this table contains details about a notification, such as which process instance and activity it is defined for, as well as the event or criteria that triggers the notification.

The information in this table should be modified only in the RapidResponse dialog boxes designated for creating and editing process notifications.

Table 6.178: Notification (ProcOrch) fields

Field name	Description	Data type	Key
Active	Determines whether the notification is active or not	Boolean	
Activity	The ID of the activity that the notification applies to. **Referenced table:** Activity	Reference	
BccRecipients	Semicolon delimited list of additional notification recipients.	String	
CcRecipients	Semicolon delimited list of additional notification recipients.	String	
NotifyOwner	Determines if the process owner is notified when the notification is run.	Boolean	
NotifyPerformers	Determines which activity performers are notified. Valid values are: • **None**—no performers are notified • **OnlyAffected**—only performers matching the notification criteria are notified • **All**—all performers are notified	Enum	
ProcessInstance	The name of the process instance this notification is for. **Referenced table**: ProcessInstance	Reference	
ProcessInstance Only	Determines if the notification is only for the process or for all activities.	Boolean	
ToRecipients	Semicolon delimited list of additional notification recipients.	String	

Table 6.178: Notification (ProcOrch) fields

Field name	Description	Data type	Key
TriggerEvent	The event that triggers the notification. Valid values are (where n is an integer defined in the TriggerEventOffset field): • **AboutToStart**—n days before ExpectedStartDate if the activity status is NotStarted • **AboutToFinish**—n days before ExpectedFinishDate if the activity status is InProgress • **ActuallyStarted**—After ActualStartDate if the activity status is InProgress • **ActuallyFinished**—After ActualFinishDate if the activity status is Finished • **LateStart**—n days after ExpectedFinishDate if the activity status is InProgress • **LateFinish**—n days after ExpectedFinishDate if the activity status is not Finished • **StartedEarly**—n days before ExpectedStartDate if the activity status is InProgress • **FinishedEarly**—n days before ExpectedFinishDate if the activity status is Finished	Enum	
TriggerEvent Offset	The number of days offset before the event will trigger the notification. For example, the notification might be triggered 2 days before an activity is supposed to start.	Integer	

OnHand table

The **OnHand** table stores the amount of inventory and other details for a part in a particular location within a warehouse. When on hand inventory is allocated to demands for pegging, high priority demands are protected. However, if there is no priority, then on hand for a part is allocated by the following fields in this table:

- ExpiryDate (earliest first)
- Date (earliest first)
- Unit Cost (least cost first)
- Quantity (smallest first)
- Location.Id and Location.Warehouse

Table 6.179: OnHand (Mfg) fields

Field name	Description	Data type	Key
BaseKey	Can optionally be used to uniquely identify each OnHand record. **Note:** If you have upgraded to Version 2015.3 and enabled record uniqueness on this table prior to the upgrade, this field is a key field. For more information, see "Key fields" on page 141.	String	
Date	Indicates the date at which inventory was received. This field can affect when given on hand inventory is allocated (as described above), and is also used in determining the appropriate currency conversion rate (if any) to apply in cost calculations. **Default value:** Past	Date	
DispositionCode	An inventory code used to determine how the part is handled in an excess or obsolete situation. This field is in the **Solutions** namespace.	String	
ExpiryDate	The date on which this inventory expires (is no longer usable). **Default value:** Undefined	Date	
ExpiryStartDate	The date when this on hand inventory begins to expire. The date provided here is rolled up the product structure through parts that use a "dependent" expiry type. For assembly parts with a **PartType.ExpiryRule** setting of "DependentStart", the earliest rolled up **ExpiryStartDate** from a component supply is then used to start expiry date calculations for the assembly supply. Thus, this field should generally be populated on supply of components that use an **ExpiryType.ProcessingRule** of "Limiting". **Note:** This field was added in Version 2016.2, Service Update 6.	Date	
Location	The stocking or bin location where the inventory is located. **Referenced table:** Location **Reference Syntax:** Location.Warehouse.Id, Location.Id **Note:** If you have upgraded to Version 2015.3 and enabled record uniqueness on this table prior to the upgrade, this field is a key field. For more information, see "Key fields" on page 141.	Reference	

Table 6.179: OnHand (Mfg) fields

Field name	Description	Data type	Key
Model	The model that corresponds to this material. Use the default model (for example, the None model) if no model is associated with this inventory record. This field is ignored unless Part.MUEPoolNettingType.ModelRule is 'Net'. This field supports Model and Unit- Effectivity analytics. For implementations not using these analytics, all supplies and demands are treated as being the None model. **Referenced table:** Model	Reference	
Part	The part number of the inventory. **Referenced table:** Part **Note:** If you have upgraded to Version 2015.3 and enabled record uniqueness on this table prior to the upgrade, this field is a key field. For more information, see "Key fields" on page 141.	Reference	
Pool	The pool that owns this material. Use the default pool (Unpooled pool) if no pool is associated with this inventory record. This field is ignored unless is 'Net'. **Referenced table:** Pool **Note:** If the Pool capability is not enabled, all supplies and demands are treated as being in the Unpooled pool.	Reference	
Quantity	The amount in stock. **Default value**: 0	Quantity	
StartUnit	The unit number corresponding to the first item in this inventory. The quantity should be one if Part.MUEPoolNettingType.UnitRule is 'Net' (the entire quantity is treated with the same StartUnit number). **Default value**: -1 **Note:** This field supports the Model-Effectivity, and Unit-Effectivity analytics, and is ignored if Model-Unit Effectivity is not enabled.	Integer	
Type	A value that determines whether the stock or inventory is considered in netting. This field references the **OnHandType** table. For information about this table, see "OnHandType table" on page 768. **Referenced table:** OnHandType	Reference	
UnitCost	Unit cost for parts in this inventory store. If UnitCost is zero, then inventory is valued at Part.StdUnitCost. Negative values are treated as zero. **Default value:** 0	Money	

OnHand table – calculated and set fields

The following describes the calculated and set fields in the OnHand table. For an introduction to this table, and descriptions of its input fields, see "OnHand table" on page 404.

Table 6.180: Calculated OnHand (Mfg) fields

Field name	Description	Data type	Key
ExpiringQuantity	The amount of this nettable inventory that will not be used before the **ExpiryDate**.	Date	

Operation table

The Operation table identifies each of the operations required in the production of a part. These records describe the order of the operations, the duration of the operations and any differences (or overrides) in capacity available at the work center during the processing of this operation.

This table is maintained for backwards compatibility and the **CRPOperation** table should be used for new purposes. The **CRPOperation** table contains most of the fields found on this table as well as additional fields to support functionality such as parallel operations and tear down time.

Table 6.181: Operation (Mfg) fields

Field name	Description	Data type	Key
BatchQuantity	The number of units that must be completed by this operation before the next operation in the sequence can begins processing the order. If set to zero, then the **Type.BatchQuantityRule** setting for the next operation in the sequence determines how that value is interpreted (either the entire operation or just a single unit in the operation must finish before moving to the next operation in the sequence). For more information about batch quantities, see "Overlapping operations" on page 1527. **Default value**: 0	Quantity	
BaseKey	Can optionally be used to uniquely identify each Operation record. **Note:** If you have upgraded to Version 2015.3 and enabled record uniqueness on this table prior to the upgrade, this field is a key field. For more information, see "Key fields" on page 141.	String	
Description	The description of the operation. **Default value**: blank string	String	

Table 6.181: Operation (Mfg) fields

Field name	Description	Data type	Key
EffectiveInDate	Date this record becomes effective. All operations in the routing are selected for effectivity based on the start date of the work order (scheduled receipt or planned order). That is, the entire sequence of operations is determined at the start of the order. **Default value**: Undefined	Date	
EffectiveOutDate	Date this record expires. All operations in the routing are selected for effectivity based on the start date of the work order (scheduled receipt or planned order). That is, the entire sequence of operations is determined at the start of the order. **Default value**: Undefined	Date	
EndUnit	The end of the unit range to which this operation record applies. The end unit is either included in the range or excluded depending upon the values of the OperationType EffectivityRule and DependentUnitRule. EndUnit is ignored unless MUERule is **Unit** or **ModelUnit**. Every supply will be seen as being before EndUnit if EndUnit is <0. **Default value**: -1	Integer	
Model	The model to which the operation record applies. The Model value is ignored unless the MUERule for the OperationType associated with this record is **Model** or **ModelUnit**. **Referenced table:** Model	Reference	
Number	The operation number for the operation. **Default value**: 0	Integer	
QueueTime Override	When scheduling this operation use this value for queue time instead of the queue time specified by the work center. If this field is negative, the work center value will be used. This is the number of hours to wait before the operation setup has been done and is used only if it is greater than or equal to zero. **Default value**: -1	Quantity	
Routing	The routing code for the operation. **Referenced table:** Routing **Reference Syntax**: Routing.Id, Routing.Site **Note:** If you have upgraded to Version 2015.3 and enabled record uniqueness on this table prior to the upgrade, this field is a key field. For more information, see "Key fields" on page 141.	Reference	

Table 6.181: Operation (Mfg) fields

Field name	Description	Data type	Key
RunTime	The Capacity calculations take the Operation RunTime, adjust it according to the CRP unit of measure, and then multiply by the order quantity to determine the number of hours load from each order. The MachineRunTimeUOM determines the processing of the run time. For example, multiply the operation run time by the order quantity to determine the load on the machine. This value must be greater than or equal to zero. **Default value**: 0	Quantity	
RunTimeUOM	Operation run time unit of measure. The RunTimeUOM determines how to convert the run time into standard hours per piece. **Referenced table:** CRPUnitOfMeasure	Reference	
SetupHours	Work center setup standard hours per lot for each machine. This value must be greater than or equal to zero and is the number of load hours to setup one machine required for this operation. **Default value**: 0	Quantity	
StartUnit	The beginning of the unit range to which this operation record applies. The start unit is either included in the range or excluded, depending upon the values of the OperationType EffectivityRule and DependentUnitRule. StartUnit is ignored unless MUERule is **Unit** or **ModelUnit**. Every supply will be seen as being after StartUnit if StartUnit is <0. **Default value**: -1	Integer	
TransitTime	Transit time for the operation. This value must be greater than or equal to zero and is the number of hours or days to move between operations. If the OperationType.TransitTimeSequenceRule is BeforeOperation this constitutes the time it takes to move from the previous operation to this operation. If the OperationType.TransitTimeSequenceRule is AfterOperation this is the time it takes to move from this operation to the next operation. **Default value**: 0	Quantity	
Type	The operation type. It is a reference to the OperationType table through the OperationType.Value field. **Referenced table:** OperationType	Reference	

Table 6.181: Operation (Mfg) fields

Field name	Description	Data type	Key
WaitTime Override	When scheduling this operation use this value for wait time instead of the wait time specified by the work center. If this field is negative, the effective work center value will be used. This is the number of hours to wait after the operation run has completed. It is used only if it is greater than or equal to zero. **Default value**: -1	Quantity	
WorkCenter	The WorkCenter (resource) for the operation. **Referenced table:** WorkCenter **Note:** If you have upgraded to Version 2015.3 and enabled record uniqueness on this table prior to the upgrade, this field is a key field. For more information, see "Key fields" on page 141.	Reference	

Operation table – calculated and set fields

The following describes the calculated and set fields in the Operation table. For an introduction to this table, and descriptions of its input fields, see "Operation table " on page 407.

Table 6.182: Calculated Operation (Mfg) fields

Field name	Description	Data type	Key
FirstEffectiveDate	Represents the adjusted value for the EffectiveInDate taking into account Type.EffectivityRule (for example, InclusiveExclusive). This field is always inclusive. If the record will never be effective, the dates will be Undefined.	Date	
FirstEffectiveUnit	The first unit to which this operation record applies. If Unit effectivity is not being used, this field is set to –1.	Integer	
LastEffectiveDate	Represents the adjusted value for the EffectiveOutDate taking into account Type.EffectivityRule (for example, InclusiveExclusive). This field is always inclusive. If the record will never be effective, the dates will be Undefined.	Date	
LastEffectiveUnit	The last unit to which this operation record applies. If Unit effectivity is not being used, set this field to –1.	Integer	

OperationSequence table

The **OperationSequence** table is used to identify different sequences of operations within a given routing. Each routing should have exactly one standard sequence of operations and, optionally, one or

more parallel operations that branch off the standard sequence. As such, each record in this table is uniquely identified by the combination of its **Id** and a reference to the **Routing** table. The **OperationSequence** table is then referenced by the **CRPOperation** table and thereby defines the routing and sequence to which each of the operations defined in that table belong.

Note: Prior to Version 2014.4, operations were defined in the **Operation** table which directly referenced the **Routing** table (and did not support parallel sequences). The **Operations** table still exists and any resources (such as, workbooks) based on it will continue to work, however, once a **Routing** record is referenced by a value in the **OperationSequence** table, all Operation records that reference that Routing are ignored.

Table 6.183: OperationSequence (Mfg) fields

Field name	Description	Data type	Key
BranchOperation	Used for parallel sequences only. Specifies the **CRPOperation.Id** value of the operation (in the routing's standard sequence) before which this parallel sequence should branch. If a matching **CRPOperation.Id** value cannot be found, or if this field is left blank, then the parallel sequence branches before the beginning of the standard sequence.	String	
Description	A description of this operation sequence.	String	
Id	An identifier for this operation sequence. Together with the referenced **Routing** record, this uniquely identifies a given sequence of operations.	String	Yes
ReturnOperation	Used for parallel sequences only. Specifies the **CRPOperation.Id** value of the operation (in the routing's standard sequence) after which this parallel sequence should return. If a matching **CRPOperation.Id** value cannot be found, or if this field is left blank, then the parallel sequence returns at the end of the standard sequence.	String	
Routing	The routing to which the sequence defined by this record belongs to. **Referenced table:** Routing **Reference Syntax**: Routing.Id, Routing.Site	Reference	Yes

Table 6.183: OperationSequence (Mfg) fields

Field name	Description	Data type	Key
Type	A reference to the control setting that defines processing rules for this operation sequence. For example, a **Type.ProcessingRule** value of "Standard" indicates the standard sequence of operations for a routing, while a value of "Parallel" indicates a parallel sequence. Typically, a **Routing** record should be referenced by exactly one standard operation sequence and, optionally, one or more parallel sequences. Note that if a routing does not have a standard sequence defined, all of its parallel sequences are ignored. Also, if more than one standard sequence is defined for a routing, RapidResponse designates one of them as the standard sequence and treats the others as parallel sequences. **Referenced table:** OperationSequenceType	Reference	

OperationSequence table – calculated and set fields

The following describes the calculated and set fields in the **OperationSequence** table. For an introduction to this table, and descriptions of its input fields, see "OperationSequence table" on page 410.

Table 6.184: Calculated OperationSequence (Mfg) fields

Field name	Description	Data type	Key
EffectiveBranch Operation	For parallel sequences, this returns the operation from which the parallel sequence branched off the standard sequence. Typically, this equates to the value specified in the **BranchOperation** field. However, in cases where **BranchOperation** is not populated or contains a value that does not exist in **CRPOperation.Id**, this returns the first operation in the standard sequence. Null if this record defines a standard sequence. **Referenced table:** CRPOperation	Reference	
EffectiveReturn Operation	For parallel sequences, this returns the standard sequence operation into which the parallel sequence branch returned. Typically, this is the value specified in the **ReturnOperation** field. However, in cases where **ReturnOperation** is not populated or contains a value that does not exist in **CRPOperation.Id**, this returns the last operation in the standard sequence. Null if this record defines a standard sequence. **Referenced table:** CRPOperation	Reference	
CRPOperations	Set of CRPOperation records associated with this operation sequence.	Set	

OriginatingFile table

The **OriginatingFile** table identifies data files used to provide RapidResponse input tables with data. It is used to help track records in RapidResponse back to their originating file, and supports data update and data persistence capabilities. This table is maintained internally by RapidResponse, and its records cannot be modified by RapidResponse users.

Table 6.185: OriginatingFile (Mfg) fields

Field name	Description	Data type	Key
CreationTime	Date and time when this data file was first encountered during a data import or update.	DateTime	
LastSeenTime	Date and time when this data file was last encountered during a data import or update.	DateTime	
Name	The name of a data file used to provide data to a RapidResponse input table. This table also contains records used to indicate data that was added internally by RapidResponse and now through a dedicated data file. For example, records with values of "User", "Historical", and "Auto-created" might typically be seen.	String	
RemovalTime	Date and time, if any, at which this file was no longer found.	DateTime	
Source	A reference to the OriginatingSource record that identifies the data source this file belongs to. **Referenced table:** OriginatingSource	Reference	

OriginatingSource table

The OriginatingSource table identifies data sources used to provide RapidResponse with input data. It is used to help track records in RapidResponse back to their originating file, and supports data update and data persistence capabilities. This table is maintained internally by RapidResponse, and its records cannot be modified by RapidResponse users.

Table 6.186: OriginatingSource (Mfg) fields

Field name	Description	Data type	Key
Name	The name of a data source that provided RapidResponse with data. This table also contains a record with a value of "RapidResponse Internal" that is used to indicate records added directly by users or through the automatic record creation process.	String	Yes
OriginatingFiles	Set of OriginatingFile records which reference this OriginatingSource value.	Set	

Note: The origins of records in tables that contain vector data are not recorded in this table.

OverrideMajorChangeover table

The OverrideMajorChangeover table describes the amount of constraint required to setup and cleanup when changing between production groups in a production wheel cycle.

Each record describes the changeover from one specific production group to another group. For example, the record below describes the amount of constraint required to changeover from producing Group A to producing Group B.

Field	Value
FromProductionGroup	Group A
ToProductionGroup	Group B
Cleanup	10
Setup	5

Another record is required to describe the amount of constraint required to changeover from producing Group B to producing Group A.

Field	Value
FromProductionGroup	Group B
ToProductionGroup	Group A
Cleanup	7
Setup	20

When the values are defined for a record in this table, these values override the values specified for MajorCleanup and MajorSetup in the ProductionGroup table. For more information about overriding default constraint amounts for changeovers, see "Changeover in production" on page 1697.

This table was added in Service Update 1902.

Table 6.187: OverrideMajorChangeover (Mfg) fields

Field name	Description	Data type	Key
Cleanup	The amount of constraint required to clean up after producing the group specified in FromProductionGroup. Measured in constraint units.	Quantity	
FromProductionGroup	A reference to the production group that production is changing over from. **Referenced table:** ProductionGroup	Reference	Yes
Setup	The amount of constraint required to set up production for the group specified in ToProductionGroup. Measured in constraint units.	Quantity	
ToProductionGroup	A reference to the production group that production is changing over to. **Referenced table:** ProductionGroup	Reference	Yes

Part table

The **Part** table identifies a unique part and site. A record in this table includes data such as: name, description, price, and cost data.

Table 6.188: Part (Mfg) fields

Field name	Description	Data type	Key
ABCCode	Classification based on Activity Based Costing (ABC) analysis. ABC is simply a classification of parts, usually by the extended cost of annual usage (quantity used * unit cost). **Referenced table:** ABCCode	Reference	
AfterForecast Interval	Number of calendar intervals after an actual demand date in which that demand can consume forecast (exclusive). The value specified here is taken in terms of either **PlanningCalendars.ForecastCalendar** or **PlanningCalendars.SecondCalendar** intervals as set by the control setting in the **PartType.ForecastConsumptionCalendar** field (ForecastCalendar is the default) For example, 1 means forecast can only be consumed up to the end of the current forecast or second calendar interval, 2 means forecast can be consumed up to the end of the next forecast or second calendar interval, and so on. For more information, see "Forecast consumption" on page 1431. **Default value**: 0	Quantity	

Table 6.188: Part (Mfg) fields

Field name	Description	Data type	Key
Allocation Multiple	If the part is used in fair-share or equal-share allocation, the allocated quantities will be rounded to the nearest multiple of this number. For example, if AllocationMultiple = 1.0, the quantity allocated for the part will always be rounded to the nearest whole number, such as 2.0 or 5.0 If this value is less than or equal to 0.0, the allocated quantity is not rounded. The last allocation of a fractional supply or an allocation to a fractional demand is also not rounded. **Default value**: 1.0	Quantity	
AvailableRule	Control whether normal capable-to-promise rules are used when calculating availability for the part. If this field is left null, then the part's available rule setting comes from **PartType.AvailableRule**. **Referenced table:** AvailableRule (Nullable)	Reference	
AverageQty	Average order quantity used when the value of the SafetyStockPolicy.SafetyStockRule field is OrderPointAverage, OrderPointOver, or OrderPointUnder. If SafetyStockPolicy.SafetyStockRule is OrderPointAverage, this value is the amount ordered to replenish inventory. **Default value**: 0	Quantity	
AverageSelling Price	The average selling price for this part. This can be zero if the part will never have independent demand (for example, not sold). **Default value**: 0	Money	
BeforeForecast Interval	Number of calendar intervals before an actual demand date in which that demand can consume forecast (inclusive). The value specified here is taken in terms of either **PlanningCalendars.ForecastCalendar** or **PlanningCalendars.SecondCalendar** intervals as set by the control setting in the **PartType.ForecastConsumptionCalendar** field (ForecastCalendar is the default) For example, a value of 0 means forecast can be consumed starting from the beginning of the current forecast or second calendar interval containing the demand date, 1 means forecast can be consumed from the beginning of the previous forecast or second calendar interval, 2 means forecast can be consumed from the beginning of the second forecast or second calendar interval before the actual demand, and so on. For more information, see "Forecast consumption" on page 1431. **Default value**: 0	Quantity	
BuyerCode	A text code that identifies the buyer for this part. **Referenced table:** BuyerCode **Reference Syntax:** BuyerCode.Value	Reference	

Table 6.188: Part (Mfg) fields

Field name	Description	Data type	Key
CarryingCost	The cost of holding inventory. **Default value**: 0	Money	
ConstraintShare Fence	Within each **OrderPriority** level, the number of **ConstraintAllocationCalendar** intervals out from **RunDate** in which to include this part's demands for use in the fair sharing of limited constraint availability amongst parts whose sources use common constraints. For example, if set to "0", then only demands due before **RunDate** (past due) would be eligible for constraint sharing. The window defined by this field is only applicable if the parts' **Type.ConstraintShareRule** setting is "WithinFence" and only for demands where the **OrderPriority.ConstraintAllocationRule** is "FairShare". **Default value**: - 1 (this indicates that constraint sharing logic, if enabled, applies throughout the part's entire planning horizon).	Integer	
DaysSupply Policy	A reference to the days of supply policy for this part. This policy defines time-phased (short-term and long-term) parameters used in days of supply calculations. For example, the number of days or periods of accumulated demand that planned orders should satisfy in both the short-term and long-term horizon. **Referenced table:** DaysSupplyPolicy (Nullable) **Note:** This reference was added in Version 2016.2. If Null and **PartType.UseDaysSupply** is set to "Y", then days of supply logic can still be used based on legacy fields in the **Part**, **PartType**, and **PlanningCalendar**s tables. However, those fields only support a single set of days of supply settings applicable throughout the horizon (are not time-phased). For more information about days of supply, see "Days of Supply calculations" on page 1362.	Reference	
DDMRPRule	A reference field linking to DDMRPRule control table. **Referenced table:**DDMRPRule (Nullable) **Note:** This field was added in Version 2016.2.	Reference	

Table 6.188: Part (Mfg) fields

Field name	Description	Data type	Key
DemandTime Fence	Number of units of time after the **Part.PlanningCalendar.RunDate.FirstDate** to establish a fence for controlling the use of unconsumed forecast demands. Within the demand time fence, any unconsumed forecast is ignored and not planned for by Netting (does not contribute to the total demand picture). However, any unconsumed forecast outside of the time fence does contribute to total demand and will be planned for by Netting. Values in this field should be expressed in **Part.PlanningCalendar.TimeFenceCalendar** intervals. If this is set to o (zero), then the demand time fence is placed at the RunDate and all unconsumed forecast drives demand (in cases where the RunDate does not fall on a TimeFenceCalendar marker, it set to the previous marker in the calendar). Note also that the demand time fence applies only to SalesForecast, and not to ProductionForecast. **Default value**: 0	Quantity	
Description	A description of the part. **Default value**: blank string	String	
Distribution PlanningRule	Controls whether Distribution Planning within CTP calculations can be used for the part. If the Distribution Planning rule is enabled, when a part exceeds the maximum inventory level at the sourcing site, this triggers a request for the finished goods to be transferred to a destination site before it is required. **Referenced table:** DistributionPlanningRule (Nullable) **Note:** This field was added in Version 2016.2.	Reference	

Table 6.188: Part (Mfg) fields

Field name	Description	Data type	Key
ExcessFence	The number of **PlanningCalendars.TimeUnit** intervals out from **RunDate** that defines the window for including a substitute part's demands and supplies when determining excess. This is applicable both to parts used as global substitutes (if their **Type.ExcessRule** is 'GlobalFence'), as well as parts used as BOM-level substitutes (if their **Type.ExcessRule** is 'Fence'). Within the excess window set by this field, existing supply (typically, on hand and scheduled receipts) of a substitute component is first used to satisfy any of its own demand. If any supply remains afterwards, then that "excess" can be used to satisfy demand from the parts or components for which it is substitutable. Outside of this window, supply of a substitute part or component is used to satisfy demand on a first-come, first-served basis regardless of whether the demand is its own or that of another part or component for which it is substitutable. Note that setting this field to a negative value (for example, -1) extends the excess window to the end of the planning horizon. This ensures that supplies of a substitute part or component are only ever eligible for use in substitution if they are deemed to be excess. Note also setting this field to 0 (zero) means that only demands and supplies due on **PlanningCalendars.RunDate.FirstDate** are used in determining excess. The end of the excess window is reported in the **ExcessFenceDate** field. Default value: 0	Integer	
ExpiryType	Controls how a component is used in determining the expiry date of any of its assemblies that have a **PartType.ExpiryRule** setting of "DependentStart". **Referenced table:** ExpiryType (Nullable)	Reference	
IncrementalRule	Controls whether incremental availability calculations can be performed for orders for this part. **Referenced table**: IncrementalRule	Reference	

Table 6.188: Part (Mfg) fields

Field name	Description	Data type	Key
Inventory HoldingRate	The inventory holding rate for this part (applicable to parts used in multi-echelon safety stock calculations). Together with the setting in the **MultiEchelonSafetyStockRule.CostRule** field, this is used to calculate the unit holding cost for the part. Unit holding costs are required as input by multi-echelon calculations that recommend strategic safety stock placement based on minimizing total inventory holding costs across a network of parts. This value should be expressed as a fractional percentage (typically, a value between 0 - 1). For example, if **CostRule** is set to "StdUnitCost", **StdUnitCost** is "200", and this field is ".2", then the unit holding cost for the part is $40 (20% of 200). Note that all negative values are treated the same as 0 (zero) and indicates there is no cost to holding the part in inventory. Also, values greater than 1 are allowed and imply the cost of holding the part in inventory is greater than the cost of the part itself. **Default value**: .2	Quantity	
LeadTimeAdjust	An additional term used to adjust (typically, increase) the total lead-time. Typically, this field is not used and left at zero. However, when dealing with certain enterprise systems where a fixed lead time of zero means there is actually a one-day difference between Due and StartDate, this field can be set to 1 for all affected parts **Default Value:** 0	Quantity	
MaterialCost	The cost of material associated in producing the part. **Default value**: 0 **Note:** This field is obsolete.	Money	

Table 6.188: Part (Mfg) fields

Field name	Description	Data type	Key
MinimumShelf Life	This field specifies the number of **PlanningCalendars.ExpiryCalendar** intervals that are added to either an independent demand's or consensus forecast's **DueDate** when calculating its **EarliestExpiryDate**. The EarliestExpiryDate is the date before which supplies must not expire if they are to be allotted to the demand. For example, if PlanningCalendars.ExpiryCalendar is set to "Month" and this value is set to "3", then an independent demand for this part with a DueDate of July 1, 2009 would have its EarliestExpiryDate set to October 1, 2009 (that is, any supply expiring before October 1, 2009 could not be used to satisfy the demand). For independent demands, this can be overridden on a demand basis by providing a value in the **IndependentDemand.MinimumShelfLife.** For consensus forecast demands, this can be overridden on a part customer basis by providing a value in the **MinimumShelfLife** field on either of the **PartCustomerTimePhasedAttributes** or **PartCustomer** tables. **Default value:** 0 **Note:** If a value of 0 is specified, this indicates that the **EarliestExpiryDate** should be set to the demand due date.	Integer	
MUEPool NettingType	The MUEPoolNetting type for this part. The MUEPoolNettingType value controls the model, pool and unit netting for a part. **Referenced table:** MUEPoolNettingType	Reference	
MultiEchelon SafetyStockRule	A value associated with rules that set how this part is used in multi-echelon safety stock calculations. For example, it controls whether a given part in a multi-echelon family is eligible to hold safety stock as inventory. **Referenced table:** MultiEchelonSafetyStockRule (Nullable)	Reference	
MultiLevel SearchRule	A reference to a control table value that is used to enable or disable multi-level search logic, and contains related options determining how multi-level search logic is performed when enabled. Multi-level search logic can be used to modify standard part sourcing and substitution logic to consider component availabilities when making sourcing decisions, and also modifies standard supply allotment logic to consider sibling component allotments when allocating a component part's supplies to the demands that require it. For more information, see "Multi-level search logic" on page 1863. **Referenced table:** MultiLevelSearchRule (Nullable) **Note:** If this reference is left Null, then multi-level search logic is always disabled for the part.	Reference	

Table 6.188: Part (Mfg) fields

Field name	Description	Data type	Key
Name	Part number or item number.	String	Yes
NextUnit	In conjunction with Part.MUEPoolNettingType.UnitRule field, this field controls how StartUnit is to be propagated from this part. It also determines the unit number to use as the StartUnit for planned orders and forecast to be exploded from this part. The following rules apply: • If NextUnit is < 0 and the part is not netting by unit, then that value is copied into **StartUnit** for all planned supplies. • If UnitRule = **Block**, the StartUnit of the planned supply is set to the larger of NextUnit or the StartUnit field on the demand order. • If UnitRule = **Increment,** and NextUnit >= 0, the next unit will be used to create the StartUnit of the planned order. Note that NextUnit is ignored for phantom parts. • If UnitRule = **Fixed**, every planned supply StartUnit will be set to **NextUnit**. • If UnitRule = **Net**, and Model-Unit Effectivity is enabled, the unit on planned orders is copied from the demand record. Otherwise, StartUnit is set to -1. **Default value**: -1	Integer	
NumberOf DaysSupply	• If **PartType.UseDaysSupply** is set to '**Y**' and the **DaysSupplyPolicy** reference is Null, then when creating a new planned order this field defines the period to cover requirements for as follows: • If **PartType.DaysSupplyRule** = 'FromDemand' or 'FromSupply', indicates the number of units (as defined by **Part.PlanningCalendars.TimeUnits)** to cover requirements for**.** • If **PartType.DaysSupplyRule** = 'ByPeriod' or 'ByPeriodWithPriority', indicates the number of calendar intervals (as defined by **Part.PlanningCalendars. PeriodSupplyInterval**) to cover requirements for. The quantity of the order is reduced if the resulting order exceeds **PartSource.MaximumQty**. **Default value:** 0 **Note:** A value of "0" or less in this field is treated as if it were set to "1"; that is, supply is planned to satisfy one day/interval of demand. **Note:** If the **DaysSupplyPolicy** reference is populated, then the reference record in the **DaysSupplyPolicy** table determine days of supply settings, and this field is ignored. For more information, see "Days of Supply calculations" on page 1362.	Quantity	

Table 6.188: Part (Mfg) fields

Field name	Description	Data type	Key
PartClass	The name of the part class, if any, associated with this part. For example, a part class might be finished goods, work in progress, or raw materials. These classes are used by certain application to assign planning, safety stock, and replenishment strategies. **Referenced table:** Class (Nullable) **Note:** This field is in the Solutions namespace.	Reference	
PercentSafety IntervalCount	This value corresponds to the SafetyStockPolicy.PercentSafetyInterval field. If this value is less than one, then one is used.	Integer	
PercentSafety Percent	This is used in the PercentOfDemand (and FractionOfDemand) safety calculation. The safety quantity for a period is determined by multiplying the total gross demand in that period by this percentage value (which may be a fraction or a percent, based on the SafetyStockPolicy.SafetyStockQuantityRule field). If this value is less than 0, then 0 is assumed.	Quantity	
PickPackTime	The amount of time required to pull an order for this part from inventory and prepare it for shipment to the customer. This value is used in calculating planned ship and receipt dates, as well as available ship and receipt dates, on **IndependentDemand** records. Note that if this field is set to a negative value, the **DefaultPickPackTime** field on a given **DeliveryRoute** record is used instead.	Integer	
PlannerCode	A text code that identifies the planner responsible for this part. **Referenced table:** PlannerCode **Reference Syntax:** PlannerCode.Value	Reference	
Planning Calendars	A value associated with processing rules that define the Part's Calendar behavior. This field references the PlanningCalendars table. **Referenced table:** PlanningCalendars **Reference Syntax:** PlanningCalendars.Value	Reference	

Table 6.188: Part (Mfg) fields

Field name	Description	Data type	Key
Primary Substitution Sequence	For parts configured as the primary part in a global part substitution relationship, this field can be used to define a relative preference between input supplies of that primary part and its substitutes. In global substitution logic, this value is compared against the **AlternatePart.Sequence** value(s) associated with the part's substitute(s). Lower values indicate a higher substitution preference. That is, if this value is less than or equal to the A**lternatePart.Sequence** value for a substitute, then this part's input supplies are preferred. Otherwise, if the **AlternatePart.Sequence** value for a given substitute is less than this value, then input supplies of the substitute are used up first (and planned orders will never be generated on the substitute to satisfy this part's demands). **Default value:** 0 **Note:** The specific usage of this field further depends on the primary part's **PartType.SubstitutionPreference** setting. For more information, see "Define when part substitutes are used" on page 1553.	Integer	
ProductFamily	A reference to the product family (if any) that the part belongs to. Product families can be used to enable aggregate level reporting for groups of related or similar parts. **Referenced table:** ProductFamily (Nullable)	Reference	
ProductGroup1	This field can be used to describe a product grouping with which a part is associated. For example, this could be a product family. **Default value**: blank string	String	
ProductGroup2	This field can be used to describe a different product grouping than ProductGroup1. For example, this could be a product line. **Default value**: blank string	String	
RangeOf CoverageBuffer	This field specifies a quantity to add to calculated range of coverage safety stock levels to account for some amount of expected demand variability. It is also used along with the value in the **RangeOfCoverageThresholdFactor** field to determine if the new calculated safety stock level should replace the value from the previous range of coverage interval. Applicable only to those parts where **SafetyStockPolicy.SafetyStockQuantityRule** is set to either "RangeOfCoverage", "RangeOfCoverageLeadTime" or "RangeOfCoverageTimePhased". **Default value**: 0	Quantity	

Table 6.188: Part (Mfg) fields

Field name	Description	Data type	Key
ReferencePart	Depending on how your company is using the reference part functionality, this column displays: • the name of this part as known throughout your company (a common part number or equivalent part). • the part name according to the naming conventions used in a different division. • a name used to group a product line the part belongs to. • the same value as the Name field • blank if this field is not populated in your implementation of RapidResponse **Referenced table**: ReferencePart	Reference	
SafetyLeadTime	Number of days to offset the demand due date when determining when supply should be planned to cover that demand. This is intended to protect against fluctuations in supply and demand and will impact planned order due dates as well as EffLeadTime and CumLeadTime calculations. This value should be expressed in either the part's **PlanningCalendars.TimeUnits** calendar or the Everyday/Gregorian calendar as determined by the part's **PartType.SafetyLeadTimeCalendarRule** setting. Note that a value provided in this field is only used when the **SafetyLeadTimeProfile** reference is Null. Usage of this field also depends on the setting in the **PartType.UseSafetyLeadTime** field, with additional **PartType** settings available to specify whether safety lead time should be used for specific types of demands. Also, if safety lead time should be applied to demand request dates and/or only used in cases where doing so won't make other demands worse off, then use of settings on the **OrderPriority.TwoDatePlanningRule** field should be considered. **Default value**: 0 **Note:** SafetyLeadTime is not included in NeedDate calculations. **Note:** SafetyLeadTime is ignored and not used to offset due dates for safety stock demands.	Quantity	

Table 6.188: Part (Mfg) fields

Field name	Description	Data type	Key
SafetyLeadTime Profile	A reference to a safety lead time profile that defines a series of time-phased safety lead time values for the part. If this reference if Null, then the value in the **SafetyLeadTime** field defines a single safety lead time value that is always effective for the part. Note that usage of this field depends on the setting in the **PartType.UseSafetyLeadTime** field, with additional **PartType** settings available to specify whether safety lead time should be used for specific types of demands. Also, if safety lead time should be applied to demand request dates and/or only used in cases where doing so won't make other demands worse off, then use of settings on the **OrderPriority.TwoDatePlanningRule** field should be considered. **Referenced table:** SafetyLeadTimeProfile (Nullable) **Note:** This field was added in Version 2016.2.	Reference	
SafetyStock Policy	A reference to the safety stock policies applicable to this part. For example, how are safety stock levels determined and under what conditions are those levels maintained. If this reference is left Null, then various fields on the **PartType** and **PlanningCalendars** tables (identical to those on **SafetyStockPolicy**) are used instead. **Referenced table:** SafetyStockPolicy (Nullable)	Reference	Yes
SafetyStockQty	A quantity of stock in inventory to protect against fluctuations in demand or supply. **Default value**: 0	Quantity	
Site	The site associated with this part. This field is a reference to the Value field on the Site table. **Referenced table:** Site **Note:** A value is required in this field for both Single-Site and Multi-Site installations.	Reference	Yes
SourceRule	If there are multiple active part sources defined for a part, this reference defines rules outlining how RapidResponse chooses the source to use when satisfying a planned requirement. **Referenced table:** SourceRule	Reference	

Table 6.188: Part (Mfg) fields

Field name	Description	Data type	Key
SpreadForecast Interval	Can be used to specify the number of forecast calendar intervals over which forecast spreading logic is applied to those forecast demands where the **DemandType.SpreadRule** value is "Spread". If left at the default value of zero (0) or set to a negative value, then the spreading logic is applied to demands throughout the entire planning horizon. However if set to a positive value, then the forecast spreading logic is only applied to those demands that are due within that number of **Part.PlanningCalendar.ForecastCalendar** intervals out from the RunDate. **Default value**: 0	Integer	
StdUnitCost	The cost to produce this part. Includes all material, labor, and overhead costs. **Default value**: 0	Money	
Substitution Tolerance	When faced with demand for the primary part in a substitute part relationship, this is the number of **PlanningCalendars.SubstitutionTolerance Calendar** intervals out from the demand date to look for existing supply of one part before supply from other parts is considered. For example, if the primary part's **PrimarySubstitutionSequence** value is less than or equal to the **AlternatePart.Sequence** for a given substitute, this defines the number of **SubstitutionToleranceCalendar** intervals out from the demand date to look for existing input supply of the primary part before considering supply from the substitute. However, if the primary part's **PrimarySubstitutionSequence** value is strictly greater than the **AlternatePart.Sequence** for a given substitute, then this is instead the number of **SubstitutionToleranceCalendar** intervals out from the primary part's demand date to look for (use up) existing supply of the substitute before supply from the primary part is considered. **Default value:** 0	Integer	
SupplyShare Fence	Within each **OrderPriority** level, the number of **AllocationCalendar** intervals out from the **RunDate** in which this part's demands are eligible for the fair or equal sharing of limited supplies. For example, if set to "0", then only demands due before **RunDate** (past due) would be eligible for supply sharing. The window defined by this field is only applicable if the parts' **Type**.**SupplyShareRule** setting is "WithinFence", and only for demands where the **OrderPriority.AllocationRule** is set to either "FairShare" or "EqualShare". **Default value**: - 1 (this indicates that supply sharing logic, if enabled, applies throughout the part's entire planning horizon).	Integer	

Table 6.188: Part (Mfg) fields

Field name	Description	Data type	Key
Type	A value that is associated with processing rules that defines the part's behavior. This field references the PartType table. For more information about this table, see "PartType table" on page 809. **Referenced table:** PartType	Reference	
UnitOfMeasure	The stock and purchased units in which quantities of this part are measured. **Referenced table:** UnitOfMeasure	Reference	
Unsatisfied Demand Tolerance	Specifies the part's tolerance level for late or unsatisfied demands. This field should be expressed in **PlanningCalendars.ForecastCalendar** intervals and is used in both partial planning (Netting) and on-time reallocation logic (CTP). If using partial planning logic (**DemandType.PlanningRule** is set to "Partial"), demands or demand portions that cannot be planned within the lateness tolerance are left unsatisfied and not planned. In other words, this field indicates the number of forecast intervals after it's due date upon which a demand should be given up on if supply cannot be planned for it. If using on-time reallocation logic (**PartType.OnTimeAllocationRule** is set to "ImproveWithTolerance"), supply quantities that are allocated to demands late and beyond tolerance can be reallocated. The goal of the reallocation process is improving the on-time quantity on late demands. But these reallocations also have the potential to make the available date on some late demands worse (later) than they otherwise would be. Thus, this field indicates the number of forecast intervals past its due date at which a late demand's overall available date is less important than improving the on-time quantity of late demands. **Default value**: 0 (indicates that the part's lateness tolerance is at the end of the current forecast calendar interval; for example, if the forecast calendar was set to Everyday this would imply any late demand is considered beyond tolerance). **Note:** This field was added in Version 2016.2, and its usage extended in Version 2016.2, Service Update 27.	Integer	

Part table – calculated and set fields

The following describes the calculated and set fields in the Part table. For an introduction to this table, and descriptions of its input fields, see "Part table " on page 415.

Note: When pool-based netting flow-to-common logic is enabled, those calculated fields that report a sum of something (for example, **TotalDemand** or **TotalSupply**) are summed across all pools whereas those fields that report the first of something (for example, **FirstShortageDate** or **FirstNeededSupplyDate**) return the first value across and from just one of those pools.

Table 6.189: Calculated Part (Mfg) fields

Field name	Description	Data type	Key
AlternatePrimary Part	The primary part this part can be used interchangeably with. **Referenced table**: Part	Reference	
AverageFirst YearInProcess	Calculated to show work in process (WIP) for supplies starting earlier than RunDate + 365 days. Calculated as 1/365 * the sum over scheduled receipts and planned orders based on SupplyType.Source. If SupplyType.Source is: • **Buy**—If **SupplyType.BuyInProcessRule** is set to **IncludeDockToStock**, this field is calculated as StockUnitQuantity * (ReschedDate - ReschedDockDate). Otherwise, it is set to zero. • **Make**—this field is calculated as: StockUnitQuantity * (ReschedDate - CalcStartDate). • **Transfer**—this field is calculated as: StockUnitQuantity * (ReschedDate - (ShipDate - PreShipLT using source time units)).	Quantity	
AverageFirst YearInventory	Average inventory level at the end of the day over the first 365 days. Useful for inventory turns calculations.	Quantity	
Constrained Demand	Total demand to be satisfied up to RunDate + 365 days. Uses AvailableDate for independent demands and SynchronizedDate for dependent requirements.	Quantity	
Constrained External Demand	The total units of external demand with AvailableDate before RunDate + 365. (excludes intersite demand).	Quantity	

Table 6.189: Calculated Part (Mfg) fields

Field name	Description	Data type	Key
ConstrainedIn Process	Projects the work in process (units of supply) between the time an order is started (shipped for transfer) and received into inventory. This calculation is based on supplies with AvailableStartDate earlier than RunDate + 365 days, and is influenced by the value of SupplyType.Source as shown in the following list: • **Buy**—If **SupplyType.BuyInProcessRule** is set to IncludeDockToStock, this field is calculated as StockUnitQuantity * (AvailableDate - AvailableDockDate). Otherwise, set to zero. • **Make**—this field is calculated as StockUnitQuantity * (AvailableDate - AvailableStartDate). • **Transfer**—this field is calculated as StockUnitQuantity * (AvailableDate - (AvailableShipDate - PreShipLT using source time units)).	Quantity	
Constrained IntersiteDemand	The total demand which acts like independent demand from another site with AvailableDate before RunDate + 365 days.	Quantity	
Constrained Inventory	Projects average daily inventory (unit) balance based on supply AvailableDate and demand SynchronizedDate (greater of EffDueDate and AvailableDate for independent demands).	Quantity	
CumLeadTime	The time from ordering all the components, to the lowest level of the structure, until the current part can be used to satisfy demand. This calculation is done only within a part's site. For multi-site cum lead time calculations (that is, calculations that consider transfer part sources), use the **MultiSiteCumLeadTime** field. For more information about lead time calculations, see "Lead time calculations" on page 1307. **Note:** Any lead time associated with phantom assemblies will not be included in the calculation of this value. **Note:** If using time-phased lead time, then the lead times effective for the primary part source at the latter of the part's **RunDate** or **PartSource.FirstEffectiveDate** are used in this calculation.	Quantity	

Table 6.189: Calculated Part (Mfg) fields

Field name	Description	Data type	Key
DaysSupply FenceDate	The date fence that indicates the transition point between short-term and long-term days of supply settings. That is, before this date the short-term days of supply settings are used, and on or after this date the long-term days of supply settings are used. This field is only populated if the part has a non-Null reference in the **DaysSupplyPolicy** field. **Note:** This field was added in Version 2016.2.	Date	
DecoupledLeadTime	This calculated field contains the multi-site cumulative lead time between buffer points. The calculation will follow the same logic as multi-site cumulative lead time, but the calculation will stop at any decouple points. **Note:** This field was added in Version 2016.2. **Note:** Only primary part source is considered for this calculation. DecoupledLeadTime calculation for make parts: EffectiveLeadTime + Max (NON-Decoupling-Point component's DLT) DecoupledLeadTime calculation if transfer part is DDMRP part: EffectiveTransferLeadTime DecoupledLeadTime calculation if transfer part is regular part: EffectiveTransferLeadTime + TransferPart's DLT	Integer	
DTFDate	The date of the demand time fence. Calculated from **RunDate** by adding the number of intervals specified in **DemandTimeFence** (based on the **PlanningCalendars.TimeFenceCalendar**). If set to 0, then this demand time fence is placed at **RunDate** (or if the RunDate does not fall on a TimeFenceCalendar marker, than it set to the previous marker).	Date	
EffectiveOrder PointDateRule	Indicates the **OrderPointDateRule** setting that is effective for this part. Valid values are: • Due • Start The effective value comes from the corresponding field on the **SafetyStockPolicy** reference (if not Null) or else the **PartType** reference. Refer to the field description on either of those tables for more information.	String (Enum)	

Table 6.189: Calculated Part (Mfg) fields

Field name	Description	Data type	Key
EffectiveOrder PointIncrease	Indicates the **OrderPointIncrease** setting that is effective for this part. Valid values are: • Calculate • Ignore • Sum • SumOffset The effective value comes from the corresponding field on the **SafetyStockPolicy** reference (if not Null) or else the **PartType** reference. Refer to the field description on either of those tables for more information.	String (Enum)	
EffectivePercent SafetyInterval	The **PercentSafetyInterval** calendar that is effective for this part. This returns the calendar value referenced through **SafetyStockPolicy.PercentSafetyInterval** (if those references are not Null) or else **PlanningCalendars.PercentSafetyInterval**. Refer to the field description on either of those tables for more information. **Referenced table:** Calendar	Reference	
EffectiveRange OfCoverage	The **RangeOfCoverage** profile that is effective for this part. This returns the range of coverage profile value that is referenced through the **SafetyStockPolicy.RangeOfCoverage** field (if those references are not Null) or else **PlanningCalendars.RangeOfCoverage**. Refer to the field description on either of those tables for more information. **Referenced table:** RangeOfCoverage	Reference	
EffectiveSafety StockDateRule	Indicates the **SafetyStockDateRule** setting that is effective for this part. Valid values are: • FirstDemand • FirstDemandOrLeadTime • FirstDemandOrRunDate • FirstDemandOrPast • LeadTime • Past • RunDate The effective value comes from the corresponding field on the **SafetyStockPolicy** reference (if not Null) or else the **PartType** reference. Refer to the field description on either of those tables for more information.	String (Enum)	

Table 6.189: Calculated Part (Mfg) fields

Field name	Description	Data type	Key
EffectiveSafety StockQuantityRule	Indicates the **SafetyStockQuantityRule** setting that is effective for this part. Valid values are: • FixedQuantity • FractionOfDemand • PercentOfDemand • RangeOfCoverage • RangeOfCoverageLeadTime • TimePhasedQuantity • TimePhasedQuantityToLatest The effective value comes from the corresponding field on the **SafetyStockPolicy** reference (if not Null) or else the **PartType** reference. Refer to the field description on either of those tables for more information.	String (Enum)	
EffectiveSafety StockRule	Indicates the **SafetyStockRule** setting that is effective for this part. Valid values are: • Always • Ignore • IfDemand • IfActivity • OrderPointAverage • OrderPointOver • OrderPointUnder • Soft The effective value comes from the corresponding field on the **SafetyStockPolicy** reference (if not Null) or else the **PartType** reference. Refer to the field description on either of those tables for more information.	String (Enum)	
EffLeadTime Adjust	Lead time adjustment used based upon the **LeadTimeAdjust** field and the Order Policy values.	Quantity	
EffSafetyLead Time	The effective safety lead-time value for this part. Returns the value in **SafetyLeadTime** unless either **PartType.UseSafetyLeadTime** is set to "N" or **SafetyStockPolicy.SafetyStockRule** is set to one of "OrderPointAverage", "OrderPointUnder", or "OrderPointOver" in which case it returns zero (0).	Quantity	

Table 6.189: Calculated Part (Mfg) fields

Field name	Description	Data type	Key
EndingSafety Stock	The safety stock level in effect at the end of the planning horizon. This is the latest safety stock level calculated for this part by RapidResponse. For information about how RapidResponse determines safety stock levels, see "Safety stock calculations" on page 1402. For order point parts (that is, parts where **SafetyStockPolicy.SafetyStockRule** is either 'OrderPointUnder', 'OrderPointOver, or 'OrderPointAverage), this field returns the latest order point threshold calculated for the part.	Quantity	
ExcessFenceDate	The date that marks the end of the excess window applicable to either global or BOM-level part substitution. Within this window, a substitute part or component's current supplies will be used to satisfy all of its own demand before that of any part it is a substitute for (thus, only excess supply is available for use in substitution). Beyond this date, a substitute part's current supplies will satisfy the demands that require them first, regardless of whether the demands are its own or come from another part. Calculated based on the **Part.ExcessFence** and **PartType.ExcessRule** fields.	Date	
FirstNeeded SupplyDate	The date when the on hand inventory of the part will run out, that is the day when a supply other than on hand is needed to satisfy demand by the scheduled due date.	Date	
FirstShortage Date	The earliest date that inventory will drop below zero (not safety stock) if no rescheduling or new orders are generated.	Date	
FirstYearExternal Demand	The total units of external demand due before RunDate + 365 (within the next year). Includes independent demand and unconsumed forecast for real parts.	Quantity	
FirstYearIntersite Demand	The total demand which acts like independent demand from another site with DueDate before RunDate + 365.	Quantity	
IsPhantom	A flag to tell if the part will blow through (ignore processing of) all its dependent demand. 1 means all dependent demand is bypassing, 0 means any dependent demand from bills that are not marked as blow through will be processed.	Integer	
LowLevelCode	Lowest level at which this part is used as a component in any BOM structure. 0 indicates a top level part.	Integer	
MEIOFamily	The part that is the head of this part's MEIO family.	Reference	

Table 6.189: Calculated Part (Mfg) fields

Field name	Description	Data type	Key
MultiSiteCum LeadTime	The amount of time required from ordering all components, down to the lowest level of the product structure, until the part can be used to satisfy demand. This field uses a calculation similar to the **CumLeadTime** field, but it also follows product structures across site boundaries. That is, if a product structure contains a part with a primary supply type of "transfer", then lead time associated with the transfer part and its components is included in the value reported in this field. Because this field sums together different lead time values without specifying the calendar to be used in the calculation, it is possible that the different lead time values summed when a product structure crosses site boundaries may not all use the same calendar. Therefore, depending on the calendars used at different sites, this field may not always return the expected result. For more information about lead time, see "Lead time calculations" on page 1307. **NOTE**: If using time-phased lead time), then the lead times effective for the primary part source at the latter of the part's **RunDate** or **PartSource.FirstEffectiveDate** are used in this calculation.	Quantity	
MultiSiteLow LevelCode	The level of the longest path from the part, considering all bill of material structures including transfer parts, to a top level part. Top level parts have a level of 0.	Quantity	
PrimaryPart Source	Reference to the primary PartSource record. The primary record is found as the first PartSource record after sorting by: • If (Part.PlanningCalendars.RunDate.FirstDate >=PartSource.FirstEffectiveDate AND Part.PlanningCalendars.RunDate.FirstDate <= PartSource.LastEffectiveDate) 0 1 • PartSource.Priority (if Ascending) or -1*PartSource.Priority (if Descending) • PartSource.Target (descending) • PartSource.FirstEffectiveDate • PartSource.Source.Supplier.ID PrimaryPartSource = <NULL> if there is no PartSource record for the part. For information about part source selection, see "Planned orders" on page 1343. **Referenced table:** PartSource	Reference	

Table 6.189: Calculated Part (Mfg) fields

Field name	Description	Data type	Key
PrimarySupply Type	The value of **PrimaryPartSource.Type.PlannedOrderSupplyType**. This is a calculated reference provided to simplify finding whether a part is: • Make • Buy • Transfer **Referenced table:** SupplyType	Reference	
TotalAllocations	Total quantity of allocations used in netting.	Quantity	
TotalByProduct Supply	Total quantity of supply for this part that was generated as a by-product residual to the production of a primary product.	Quantity	
TotalCoProduct Supply	Total quantity of supply for this part that was generated as a co-product alongside the production of a primary product.	Quantity	
TotalDemand	Total quantity of demand processed by netting.	Quantity	
TotalEffPlanned Order	The total of the expected quantity to receive into inventory of all planned orders for the part. This calculation handles unit of measure (UOM) conversion, and scrap/yield.	Quantity	
TotalEff Scheduled Receipt	The total of the expected quantity to receive into inventory of all scheduled receipts for the part. This calculation handles unit of measure (UOM) conversion, and scrap/yield.	Quantity	
TotalFirstYear Demand	Total of demand that must be shipped in the first 365 days. Useful for inventory turns calculations.	Quantity	
TotalForecast	The total of all forecast records.	Quantity	
Total Independent Demand	Total quantity of independent demand used in netting. This does not include forecasted independent demands. That is, IndependentDemand records where **Order.Type.ProcessingRule** is set to "SalesForecast" are excluded from this calculation.	Quantity	
TotalIndependent DemandCount	The number of independent demand records that are reflected in the TotalIndependentDemand field (for example, records that were not ignored in MRP processing).	Quantity	

Table 6.189: Calculated Part (Mfg) fields

Field name	Description	Data type	Key
TotalNeeded Supply	Total quantity from input supply (including on hand, inventory transfers, and scheduled receipts) that are needed to meet demand. This value is in inventory units, and is not shrunk in consideration of the yield factor. This summarization is faster than doing a summarized query on the Supply table.	Quantity	
TotalNettable OnHand	Total quantity of OnHand for the part that is available to meet demand. This summarization is faster than doing a summarized query on the OnHand table.	Quantity	
TotalNew Allocations	Total quantity of NewAllocations used in netting.	Quantity	
TotalNon Nettable OnHand	Total quantity of OnHand for the part that is not available for satisfying demand.	Quantity	
TotalPlanned Allocations	Total quantity of PlannedAllocations used in netting.	Quantity	
TotalPlanned Order	Total quantity of planned orders being requested. This value is in inventory units, and is not shrunk in consideration of the yield factor. This summarization is faster than doing a summarized query on the planned order table.	Quantity	
TotalPlanned OrderCount	The total number of PlannedOrder records that are reflected in the TotalPlannedOrder field (for example, the number of planned orders requested).	Quantity	
TotalSupply	Total quantity from ScheduledReceipt records that are available to meet demand.This value is in inventory units, and is not shrunk in consideration of the yield factor. This summarization is faster than doing a summarized query on the Supply table.	Quantity	
TotalSupply Count	The total number of ScheduledReceipt records that are reflected in the TotalSupply field (for example, the number of scheduled receipts available to meet demand).	Quantity	
Total Unconsumed Forecast	The amount of forecast that is not covered by actual sales demand.	Quantity	

Table 6.189: Calculated Part (Mfg) fields

Field name	Description	Data type	Key
Validation Differences RollUpSum	Sum of ValidationDifferencesThisLevel for this part and all of its components, including all part sources. This field supports data validation and is intended for internal use only.	Integer	
Validation Differences RollUpCount	Count of parts below and including this one that have validation differences. This field supports data validation and is intended for internal use only.	Integer	
Validation Differences ThisLevel	Count of all dates on which the sum of PlannedOrder quantities differs from the sum of BaselinePlannedOrder quantities. This field supports data validation and is intended for internal use only.	Integer	
Activity	Set of Activity records.	Set	
Allocations	Set of Allocation records belonging to this part.	Set	
Allotment Override Details	Set of AllotmentOverrideDetail records that reserve supply of this component part.	Set	
AlternateParts	A set of parts from the AlternatePart table that can be substituted for this part in production or planning calculations.	Set	
Alternate Routings	A set of alternate Routing records that are used for informational purposes only at this time.	Set	
AssumptionBy Parts	Set of assumptions associated with this part. **Referenced table:** AssumptionByPart	Set	
AvailableTo Promise	Set of AvailableToPromise (ATP). ATP is the uncommitted portion of Inventory and scheduled receipts (for example, not satisfying actual demand).	Set	
BaselinePlanned Orders	Set of BaselinePlannedOrders records for this part.	Set	
BlowThrough NewAllocations	Set of BlowThroughNewAllocation records bypassing the netting of this part.	Set	
BlowThrough Planned Allocations	Set of BlowThroughPlannedAllocation records bypassing the netting of this part.	Set	

Table 6.189: Calculated Part (Mfg) fields

Field name	Description	Data type	Key
CoByProduct Supplies	Set of co-product and by-product supplies in the CoByProductSupply table for this part.	Set	
Collaborative Forecasts	Set of CollaborativeForecast records that reference this Part value.	Set	
Components	Set of BillOfMaterial records where this part is the assembly. This represents the set of BOM records defining the components that go into making this part.	Set	
Consensus Forecast	Set of ConsensusForecast records for this part.	Set	
Consensus ForecastDetails	Set of ConsensusForecastDetail records for this part.	Set	
CostOfGoods Solds	Set of CostOfGoodsSold records belonging to this part.	Set	
CostRollUps	Set of CostRollUp records belonging to this part.	Set	
CTPActivity	Set of CTPActivity records associated with this part.	Set	
CTPCoByProduct Supplies	Set of CTPCoByProductSupply records for this part.	Set	
CTPForecast CostInfo	Set of CTPForecastCostInfo records associated with this part.	Set	
CTPForecasts	Set of CTPForecast records associated with this part.	Set	
CTPPlanned Orders	Set of CTPPlannedOrder records associated with this part.	Set	
CTPSubstitute Supplies	Set of CTPPSubstituteSupply records associated with this part.	Set	
CustomerPart Prices	Set of CustomerPrice records containing cost details for this part.	Set	
Demand Exceptions	Set of DemandExceptions (unsatisfied demands due to expiry) for this part.	Set	

Table 6.189: Calculated Part (Mfg) fields

Field name	Description	Data type	Key
Demands	Set of Demand. Demand is the consolidation of Dependent and Independent Demands.	Set	
Dependent Consensus Forecasts	Set of DependentConsensusForecast records for this part.	Set	
Dependent Demands	Set of DependentDemand. DependentDemand is the consolidation of Allocations and the New and Planned Allocations coming into the part.	Set	
Direct Components	Set of DirectComponent records for this part.	Set	
FamilyMEIO Parts	Set of SafetyStockPart records found under a multi-echelon family with this part as the head.	Set	
FeatureMaps	Set of FeatureMap records configured for this part.	Set	
FlatBillDowns	Set of FlatBillDown records for this part (any components under this part).	Set	
FlatBillUps	Set of FlatBillUp records for this part (any assemblies where this part is used)	Set	
FlatComponents	Set of FlatComponent records for this part.	Set	
FlatConstraints	Set of FlatConstraint records for this part.	Set	
Forecast	Set of Forecast records for this part.	Set	
Forecast Consumption	Set of ForecastConsumption records for this part.	Set	
HistoricalPart KPIs	Set of HistoricalPartKPI records for this part.	Set	
IDByFeatures	Set of IndependentDemandByFeature records associated with this part.	Set	
IDByFeature Summary	Set of IndependentDemandFeatureSummary records associated with this part.	Set	

Table 6.189: Calculated Part (Mfg) fields

Field name	Description	Data type	Key
Independent Demands	Set of IndependentDemand records belonging to this part.	Set	
InProcess	Set of InProcess records for this part.	Set	
Inventory Analysis	Set of InventoryAnalysis records pertaining to this part.	Set	
InventoryCTP Analysis	Set of InventoryCTPAnalysis records pertaining to this part.	Set	
Inventory Sourcing Transfers	Set of InventoryTransfer records where this part is the transfer part.	Set	
Inventory Summarys	Set of InventorySummary records for this part.	Set	
Inventory Transfers	Set of InventoryTransfer records for this part.	Set	
LoadFLPPlanneds	Set of LoadFLPPlanned records pertaining to this part.	Set	
Maximum Inventory Results	Set of MaximumInventoryResults records pertaining to this part.	Set	
MEIODriverParts	Set of MEIODriverPart records that ultimately brought this part into a multi-echelon family.	Set	
MEIOFamilies	Set of MEIOFamilyResult records for which this part is the head.	Set	
MEIOParent Parts	Set of MEIOParentPart records that brought this part into a multi-echelon family.	Set	
MEIOStageLinks	Set of MEIOStageLink records associated with this part.	Set	
MEIOStageTime PhasedResults	Set of MEIOStageTimePhasedResult records associated with this part.	Set	
MEIOStage Results	Set of MEIOStageResult records associated with this part.	Set	

Table 6.189: Calculated Part (Mfg) fields

Field name	Description	Data type	Key
MEIOStages	Set of MEIOStage records associated with this part.	Set	
MUECumLeads	Set of MUECumLead records associated with this part.	Set	
MUEPool Validations	Set of Part_MUEPoolValidation records that define all model, unit, and pool combinations for a part with data validation differences. This field supports data validation and is intended for internal use only.	Set	
OnHands	Set of OnHand records belonging to this part.	Set	
OriginalParts	A set of AlternatePart records this part can be substituted for in production or planning calculations.	Set	
PartCustomers	Set of PartCustomer records associating this part with a customer.	Set	
PartSolutions	Set of PartSolution records belonging to this part.	Set	
PartSources	Set of PartSource records belonging to this part.	Set	
PartSuppliers	Set of PartSupplier records associating this part with a supplier.	Set	
PeriodsOf Coverage	Set of PeriodsOfCoverage records belonging to this part.	Set	
PeriodsOfCTP Coverage	Set of PeriodsOfCTPCoverage records belonging to this part.	Set	
PlannedOrders	Set of PlannedOrder recommendations for new supply orders to be generated.	Set	
PoolMap Overrides	Set of PoolMapOverride records for this part.	Set	
RangeOf Coverage PartOverrides	Set of RangeOfCoveragePartOverride records for this part.	Set	
SafetyStock Bounds	Set of SafetyStockTimePhasedBounds records for this part.	Set	

Table 6.189: Calculated Part (Mfg) fields

Field name	Description	Data type	Key
SafetyStockItem Mappings	Set of SafetyStockItemMapping records for this part.	Set	
SafetyStock Items	Set of SafetyStockItem records configured for this part.	Set	
SafetyStockParts	Set of calculated SafetyStockPart records calculated for this part.	Set	
SafetyStock Results	Set of SafetyStockResult records (recommendations) for this part.	Set	
SafetyStockTime PhasedResults	Set of SafetyStockTimePhasedResult records (recommendations) for this part.	Set	
Scheduled Receipts	Set of ScheduledReceipt records belonging to this part.	Set	
ShopKanbans	Set of ShopKanban records for the part. **Referenced table**:ShopKanban	Set	
Substitute Supplies	Set of SubstituteSupply records where this part is reported as receiving supply from a substitute.	Set	
Supplies	Set of Supply. Supply is the consolidation of ScheduledReceipts and PlannedOrders.	Set	
Supply Allocations	Set of SupplyAllocation records belonging to this part.	Set	
SupplyDemands	Set of SupplyDemand records belonging to this part.	Set	
TaskLinks	Set of TaskPartLink records associating this part with project tasks.	Set	
TimePhased Safetys	Set of TimePhasedSafety records belonging to this part.	Set	
TransferPart Sources	Set of PartSource records where this part is supplied as a transfer.	Set	
UOM Conversions	Set of PartUOMConversion table records associated with this part.	Set	

Table 6.189: Calculated Part (Mfg) fields

Field name	Description	Data type	Key
ValidatePlanned Orders	Set of ValidatePlannedOrder table records associated with this part.	Set	
WhereConsumed ForForecasts	Set of WhereConsumedForForecast records belonging to the part.	Set	
WhereConsumed ForSupplies	Set of WhereConsumedForSupply records belonging to the part.	Set	
Where Consumeds	Set of WhereConsumed table records for the part.	Set	
WhereConsumed ToHighVolume Orders	Set of WhereConsumedToHighVolumeOrder records belonging to this part.	Set	
WhereUsed	Set of BillOfMaterial records where this part is the Component. This represents the set of BOM records defining the Assemblies where this part is used.	Set	

PartCustomer table

The **PartCustomer** table supports Sales and Operations Planning in RapidResponse, and should be integrated during the initial deployment. This table identifies each unique part and customer combination provided in historical data and then used in forecast generation. It also contains certain attributes (such as, priority) to be applied across all Forecast records generated from consensus forecast for a given part and customer combination.

In cases where time-phased part customer attributes are required, the **PartCustomerTimePhasedAttributes** table can be used. Also, if it is sufficient to generate the forecast for an aggregate grouping of a given part's customers, then configuration records can be added to the **AggregatePartCustomer** table.

Table 6.190: PartCustomer (Mfg) fields

Field name	Description	Data type	Key
AutoCommit Horizon	The auto-commit horizon for this part-customer's demands. It is used to determine whether the **CustomerRequestDate** on a given demand from this part customer can be automatically committed to. This value should be expressed in intervals of the **Part.PlanningCalendars.TimeUnits** calendar, and is added to a line item's **OrderCreationDate** to determine the **AutoCommitHorizonDate**. If the line's **RequestDate** is on or after that **AutoCommitHorizonDate**, then the **DueDate** is set to the **RequestDate** and the customer request is automatically promised. Typically, this horizon will be configured to be outside of the part's lead time. If set to a value less than zero(0), then the part's default horizon from **PartSolution.AutoCommitHorizon** is used instead. **Note:** This field is in the Solutions namespace. It supports the Order Fulfillment application, and is not used in any analytic calculations.	Integer	
Customer	The customer associated with the historical demand series and/or forecast. **Referenced table**: Customer **Reference Syntax**: Customer	Reference	Yes
DemandType	The DemandType associated with consensus forecasts for this part and customer combination (for example, this can be used to set how spreading is handled for consensus forecasts. Note that regardless of the DemandType specified, RapidResponse always treats consensus forecasts as if **DemandType.ProcessingRule** is set to 'SalesForecast'. **Referenced table:** DemandType (Nullable)	Reference	
Disaggregation Calendar	A calendar that defines the periods that forecast quantities can be disaggregated into for a part customer. If this field is null, the disaggregation calendar specified in the **SOPAnalyticsConfiguration** table is used for disaggregation. For example, by default a standard monthly calendar might be used, but some customers might use a fiscal month calendar and others a weekly calendar. **Referenced table:** Calendar (Nullable)	Reference	

Table 6.190: PartCustomer (Mfg) fields

Field name	Description	Data type	Key
ExpiryOffset	Allows for the expiry requirements placed on component ingredients to be adjusted (reduced) on a part-customer basis. It specifies the number of **Part.PlanningCalendars.ExpiryCalendar** intervals to extend the minimum shelf life, and hence the calculated **EarliestExpiryDate**, before exploding demands for a given part customer down to the item's components. Thus, the expiry date on supplies used to satisfy demands for the part-customer must then satisfy this adjusted earliest expiry date. When calculated expiry dates are subsequently rolled back up the product structure, the **SupplyDemand**.**ExpiryDate** on the record reporting an allotment of supply to this top level demand is then adjusted (reduced) by the value in this field. This ensures that **ExpiryDate** reflects the limiting and part customer-specific expiry requirements on the rolled up components. Note that this field is only applicable on records for which the **MinimumShelfLife** value is provided (ignored when **MinimumShelfLife** is taken from the **Part** record). **Default value:** -1	Integer	
ForecastItem	A reference to the forecast item configuration that defines statistical forecast generation for the part and customer combination defined by this record. **Referenced table:** ForecastItem	Reference	
ForecastItemLevel	Indicates the forecast level that is defined for generating a statistical forecast for this part-customer. If you choose to forecast by aggregate part-customer, you need to set the forecast item at a level in the hierarchy that is equal to or above the aggregate part-customers. If the forecast items is set at a level that is below the aggregate part customers, you will be able to calculate the statistical forecast, but the forecast will not be recorded and the values are not available in the consensus forecast. **Note:** This field is in the Solutions namespace. It supports the Statistical Forecasting application, and is not used in any analytic calculations.	String	

Table 6.190: PartCustomer (Mfg) fields

Field name	Description	Data type	Key
FrozenHorizon	The frozen horizon for this part-customer's demands. It is used to determine a near-term window in which the **CustomerRequestDate** on a given demand from this part customer will never be automatically committed to. This value should be expressed in intervals of the **Part.PlanningCalendars.TimeUnits** calendar, and is added to a line item's **OrderCreationDate** in order to determine the **FrozenHorizonDate**. If the line's **RequestDate** is before the **FrozenHorizonDate**, then its **DueDate** is set to the later of **FrozenHorizonDate** or the **AvailableDate**, and manual intervention would be needed to pull the commitment within the frozen horizon. If set to a negative value, then the part's default horizon from **PartSolution.Frozen Horizon** is used instead. **Note:** This field is in the Solutions namespace. It supports the Order Fulfillment application, and is not used in any analytic calculations.	Integer	
MaximumNumberOfCustomerChanges	The number of customer-requested changes allowed on line items for this part customer before certain application resources apply formatting to flag the order as having reached the maximum change threshold. This might indicate further investigation of the order is required to understand the cause of all the changes. **Note:** This field is in the Solutions namespace. If a negative value is specified, then the global default from the MaximumNumberOfCustomerChanges field on the OFConfiguration table is used instead.	Integer	
MaximumNumberOfSupplyChanges	The number of supply-related changes allowed on line items for this part customer before certain application resources apply formatting to flag the order as having reached the maximum change threshold. This might indicate further investigation of the order is required to understand the cause of all the changes. **Note:** This field is in the Solutions namespace. If a negative value is specified, then the global default from the **MaximumNumberOfSupplyChanges** field on the **OFConfiguration** table is used instead.	Integer	

Table 6.190: PartCustomer (Mfg) fields

Field name	Description	Data type	Key
MinimumShelfLife	For parts configured for expiry, this is the MinimumShelfLife assigned to consensus forecasts for this part and customer combination. This represents the number of expiry calendar intervals to be added to the forecast date to determine the EarliestExpiryDate (date before which supply must not expire if it is to be used in satisfying this demand). If time-phased shelf-lifes are required, the **PartCustomerTimePhasedAttributes** table can be used (its **MinimumShelfLife** overrides this value within a given date range). Otherwise, if a negative value is provided in both this table and **PartCustomerTimePhasedAttributes**, then **Part.MinimumShelfLife** is used for this part and customer combination.	Integer	
OrderPriority	The priority assigned to consensus forecasts for this part and customer combination. Used when allocating limited supply to demands. If time-phased priorities are required, the **PartCustomerTimePhasedAttributes** table can be used. **Referenced table:** OrderPriority (Nullable)	Reference	
Part	The part associated with the historical demand series and/or forecast. **Referenced table**: Part **Reference Syntax**: Part.Name, Part.Site	Reference	Yes
Pool	The pool, if any, that consensus forecasts for this part and customer combination should belong to. **Referenced table:** Pool (Nullable)	Reference	
ToleranceProfile	The name of the tolerance profile used for this part and customer combination. Tolerance profiles define the calendars used in calculating the baseline historical demand series as well as the calendars used when calculating tolerance zones for measuring change in forecasts. **Referenced table**: ToleranceProfile (this reference is nullable in new installations of RapidResponse Version 10.1 and later).	Reference	

PartCustomer table– calculated and set fields

The following describes the calculated and set fields in the **PartCustomer** table. For an introduction to this table, and descriptions of its input fields, see "PartCustomer table" on page 444.

Table 6.191: Calculated PartCustomer (Mfg) fields

Field name	Description	Data type	Key
Effective Disaggregation Calendar	The disaggregation calendar used when disaggregating forecast quantities for this part customer. **PartCustomer.DisaggregationCalendar** is used when defined; otherwise, the disaggregation calendar specified in the **SOPAnalyticsConfiguration** table is used for disaggregation.	Reference	
Aggregates	The set of **AggregatePartCustomer** records where this part and customer combination is the aggregate part customer.	Set	
AssumptionBy PartCustomers	The set of **AssumptionByPartCustomer** records associated with this part and customer combination.	Set	
Components	The set of **AggregatePartCustomer** records where this part and customer combination is the part customer being aggregated.	Set	
Disaggregation Rates	The set of disaggregation rates calculated for the part and customer combination.	Set	
HistoricalDemand Headers	The set of **HistoricalDemandHeader** records associated with this part and customer combination.	Set	
TimePhased Attributes	Set of **PartCustomerTimePhasedAttributes** records associated with this part and customer combination	Set	

PartCustomerTimePhasedAttributes table

The **PartCustomerTimePhasedAttributes** table contains time-phased attributes (such as, priority) to be applied across all Forecast records generated from consensus forecast for a given part and customer combination. If this table contains an effective record for a part and customer combination on a given consensus forecast date, then the attributes specified in this table are applied to the Forecast record. Otherwise, if no effective record exists for a part and customer combination on a given Forecast date, then the corresponding attribute values from the **PartCustomer** table are applied instead.

This table supports Sales and Operations Planning in RapidResponse.

Table 6.192: PartCustomerTimePhasedAttributes (Mfg) fields

Field name	Description	Data type	Key
Allotment Override	A reference to the allotment override reserving component supply to consensus forecast demands for this part and customer combination. The reserved supply is allocated to consensus forecast demand(s) for part customers that reference the allotment override before it can be made available to other part customers. **Referenced table:** AllotmentOverride **Note:** This reference is nullable.	Reference	
EffectiveInDate	The date on which this set of part customer attributes become effective.	Date	
EffectiveOut Date	The date on which this set of part customer attributes is no longer effective.	Date	
ExpiryOffset	Allows for the expiry requirements placed on component ingredients to be adjusted (reduced) on a demand by demand basis. It specifies the number of **Part.PlanningCalendars.ExpiryCalendar** intervals to extend the minimum shelf life, and hence the calculated **EarliestExpiryDate**, before exploding demand down to the item's components. Thus, the expiry date on supplies used to satisfy demands for the part-customer must then satisfy this adjusted earliest expiry date. When calculated expiry dates are subsequently rolled back up the product structure, the **SupplyDemand.ExpiryDate** on the record reporting an allotment of supply to this top level demand is then adjusted (reduced) by the value in this field. This ensures that the **ExpiryDate** reflects the limiting and demand-specific expiry requirements on the rolled up components. Note that this field is only applicable on records for which the **MinimumShelfLife** value is provided (ignored when **MinimumShelfLife** is taken from the **Part** record). **Default value:** -1	Integer	
Id	A unique identifier for this record.	String	Yes

Table 6.192: PartCustomerTimePhasedAttributes (Mfg) fields

Field name	Description	Data type	Key
Minimum ShelfLife	The minimum shelf life applied to consensus forecasts within the effective date range for this part and customer combination. This field is applicable to parts configured for expiry, and represents the number of expiry calendar intervals to be added to the forecast date to determine the EarliestExpiryDate (date before which supply must not expire if being used to satisfy a demand). If a negative value is provided in this field, then the **PartCustomer.MinimumShelfLife** (if non-negative) or **Part.MinimumShelfLife** value is used instead for this part and customer combination.	Integer	
OrderPriority	The priority applied to consensus forecasts within the effective date range for this part and customer combination. Used when allocating limited supply to demands. **Referenced table:** OrderPriority	Reference	Yes
PartCustomer	A reference to the part and customer combination these attributes apply to. **Referenced table:** PartCustomer	Reference	Yes

PartMetric table

The **PartMetric** table identifies the combination for each part and metric definition generated for a specific as of date that are used in live lens and comparison scorecards.

This table was added in Version 2016.2, Service Update 19.

Table 6.193: PartMetric (Solutions) fields

Field name	Description	Data type	Key
AsOf	A reference to the date on which the part and metric definitions are generated. **Referenced table:** MetricAsOf	Reference	Yes
Metric	A reference to the metric associated with this combination of part and metric definition data. **Referenced table:** Metric	Reference	Yes
Part	A reference to the part the associated with this combination of part and metric definition data. **Referenced table:** Part	Reference	Yes

PartMetric table – calculated and set fields

The following describes the calculated and set fields in the PartMetric table. For an introduction to this table, and descriptions of its input fields, see "PartMetric table" on page 451.

Table 6.194: PartMetric (Solutions) fields

Field name	Description	Data type	Key
PartMetricValues	The set of part calculations that belong to this combination of part and metric definition data. **Referenced table:** PartMetricValues	Set	

PartMetricValues table

The **PartMetricValues** table stores the part calculations for metrics used in live lens and comparison scorecards.

This table was added in Version 2016.2, Service Update 19.

Table 6.195: PartMetricValues (Solutions) fields

Field name	Description	Data type	Key
Date	The date associated with this calculation.	Date	Yes
PartMetric	A reference to the part and metric definition combination associated with this calculation. **Referenced table:** PartMetric	Reference	Yes
Quantity	The quantity for the metric. The value in this field is used if Metric.ValueType= 'Quantity'. For more information, see "Metric table" on page 399.	Quantity	
Value	The money value for the metric. The value in this field is used if Metric.ValueType= 'Money'. For more information, see "Metric table" on page 399.	Money	

PartSequence table

The **PartSequence** table identifies the sequence assigned to a part made in a production wheel.

This table was added in Service Update 1902.

Table 6.196: PartSequence(Mfg) fields

Field name	Description	Data type	Key
Part	The part associated with this part sequence. **Referenced table:** Part	Reference	Yes
ProductionWheel	The production wheel associated with this part sequence. **Referenced table:** ProductionWheel	Reference	Yes
Sequence	The order a part is processed in the production wheel. Smaller numbers are processed first.	Integer	

PartSolution table

This table stores application-specific information related to a part. The values in this table are used by resources specific to certain application solutions such as Distribution Requirements Planning, Order Fulfillment, and Master Production Scheduling, and have no impact on analytic results.

For example, several fields in this table hold part-level parameters used by resources belonging to the MPS application such as the duration of the window during which it is recommended not to make changes to MPS orders. However, these fields are not used or required by the Master Production Scheduling analytic.

This table is not shown on the RapidResponse Data Model for Import poster.

Table 6.197: PartSolution (Solutions) fields

Field name	Description	Data type	Key
AutoCommit Horizon	The default auto-commit horizon for this part's demands. It is used to determine whether the **CustomerRequestDate** on a given demand for this part can be automatically committed to. This value should be expressed in intervals of the **Part.PlanningCalendars.TimeUnits** calendar, and is added to a line item's **OrderCreationDate** to determine the **AutoCommitHorizonDate**. If the line's **RequestDate** is on or after that **AutoCommitHorizonDate**, then the **DueDate** is set to the **RequestDate** and the customer request is automatically promised. Typically, this horizon will be configured to be outside of the part's lead time. If an auto-commit horizon is defined for a given part customer in **PartCustomer.AutoCommitHorizon**, then it is used instead. **Note:** This field is in the Solutions namespace. It supports the Order Fulfillment application, and is not used in any analytic calculations.	Integer	
DemandPlanner Code	Identifies the demand planner responsible for this part. **Referenced table**: PlannerCode (Nullable)	Reference	
DistributionPlanner Code	Identifies the distribution requirements planner responsible for this part. **Referenced table**: PlannerCode (Nullable) **Note:** This field was added in Version 2016.2, Service Update 5.	Reference	
DRPCalendar	A reference to the Calendar that is specified for DRP settings for this part and site. If a calendar is specified in this field, it overrides the calendar set by **DRPConfiguration.Calendar**. **Referenced table**: Calendar **Note:** This field was added in Version 2016.2, Service Update 5.	Reference	

Table 6.197: PartSolution (Solutions) fields

Field name	Description	Data type	Key
DRPFrozenWindow	Indicates the length of the DRP frozen window for the part. This value should be expressed in **DRPConfiguration.Calendar** intervals. A value of "0" can be used to indicate that the part does not have a frozen window. A value of "-1" can be used to indicate that the global default from the **DRPConfiguration.DRPFrozenWindow** field should be used. **Default value**: -1 **Note:** This field was added in the Version 2016.2, Service Update 5.	Integer	
DRPHorizon	Indicates the length of the DRP horizon for the part. This value should be expressed in **DRPConfiguration.Calendar** intervals. Within this horizon, the distribution requirements planner is actively executing the distribution requirements plan, such as aligning orders to demand and firming planned orders. A value of "0" can be used to indicate that the part does not have a DRP horizon. A value of "-1" can be used to indicate that the global default from the **DRPConfiguration.DRPHorizon** field should be used. **Default value**: -1 **Note:** This field was added in the Version 2016.2, Service Update 5.	Integer	
DRPPlanning Horizon	Indicates the length of the DRP planning horizon for the part. This value should be expressed in **DRPConfiguration.Calendar** intervals. The DRP planning horizon specifies the length of time that extends into the future for long-term planning. A value of "0" can be used to indicate that the part does not have a DRP planning horizon. A value of "-1" can be used to indicate that the global default from the **DRPConfiguration.PlanningHorizon** field should be used. **Default value**: -1 **Note:** This field was added in Version 2016.2, Service Update 5.	Integer	

Table 6.197: PartSolution (Solutions) fields

Field name	Description	Data type	Key
FrozenHorizon	The default frozen horizon for this part's demands. It is used to determine a near-term window in which the **CustomerRequestDate** on a given demand for this part will never be automatically committed to. This value should be expressed in intervals of the **Part.PlanningCalendars.TimeUnits** calendar, and is added to a line item's **OrderCreationDate** in order to determine the **FrozenHorizonDate**. If the line's **RequestDate** is before the **FrozenHorizonDate**, then its **DueDate** is set to the later of **FrozenHorizonDate** or the **AvailableDate**, and manual intervention would be needed to pull the commitment within the frozen horizon. If a frozen is defined for a given part customer in **PartCustomer.FrozenHorizon** then it is used instead. **Note:** This field is in the Solutions namespace. It supports the Order Fulfillment application, and is not used in any analytic calculations.	Integer	
InventoryPlanner Code	Identifies the inventory planner responsible for this part. **Referenced table**: PlannerCode (Nullable)	Reference	
KeyPart	Indicates whether the part is a key part. Key parts are included in S&OP analysis and can be used to indicate limitations to planning. **Default value:** N	Boolean	
MasterScheduler Code	Identifies the master scheduler responsible for this part. **Referenced table**: PlannerCode (Nullable)	Reference	
MPSAutoFirm Window	Indicates the number of calendar intervals after the end of the MPS planning horizon where a command automatically converts planned orders for the part into firm MPS orders. This value should be expressed in intervals of the **SOPAnalyticsConfiguration.CycleCalendar**. A value of "0" can be used to indicate that the part does not have an auto firm window. A value of "-1" can be used to indicate that the global default from the **MPSConfiguration.AutoFirmWindow** field should be used for that part. **Default value**: -1	Integer	

Table 6.197: PartSolution (Solutions) fields

Field name	Description	Data type	Key
MPSFrozenWindow	Indicates the length of the MPS frozen window for the part. This value should be expressed in **MPSConfiguration.Calendar** intervals. A value of "0" can be used to indicate that the part does not have a frozen window. A value of "-1" can be used to indicate that the global default from the **MPSConfiguration.FrozenWindow** field should be used. **Default value:** -1	Integer	
MPSHorizon	Indicates the length of the MPS planning horizon for the part. This value should be expressed in **MPSConfiguration.Calendar** intervals. Within the horizon defined by this field, MPS orders are assumed to be fully under the authority of the master scheduler. A value of "0" can be used to indicate that the part does not have an MPS planning horizon. A value of "-1" can be used to indicate that the global default from the **MPSConfiguration.Horizon** field should be used. **Default value:** -1	Integer	
Part	The part this set of application solution settings applies to. **Referenced table:** Mfg::Part	Reference	
SafetyStock ItemCreate	Indicates if a part will be used to create a safety stock item. Valid values are: • **Accepted**—Indicates that the part has been reviewed and will be used to create a safety stock item. • **Rejected**—Indicates that the part has been reviewed and will not be used to create a safety stock item. • **Undecided**—indicates that the part has not been reviewed. If no value is specified, the default value for this field is used. **Default value**: Undecided **Note:** This field was added in Version 2016.2, Service Update 10 and is in the Solutions namespace. It supports the Inventory Planning and Optimization application, and is not used in any analytic calculations.	String (Enum)	
StorageType	The storage type that is associated with this part. Storage types define the storage locations that are used in the Distribution Requirements Planning application. For example, a storage type value could be Freezer or Cage. **Referenced table:** StorageType	Reference	

Table 6.197: PartSolution (Solutions) fields

Field name	Description	Data type	Key
Strategy	The manufacturing strategy for the part, such as make to stock, make to order, and so on. The manufacturing strategy can be used to determine whether appropriate planning, inventory, and supply chain strategies are being used for the part.	String	

PartSolution – calculated and set fields

The following describes the calculated and set fields in the **PartSolution** table. For an introduction to this table, and descriptions of its input fields, see "PartSolution table" on page 453.

Table 6.198: Calculated PartSolution (Solutions) fields

Field name	Description	Data type	Key
EffectiveDRP FrozenWindow	The length of the DRP frozen window that is effective for this part. If a non-negative value is provided in **DRPFrozenWindow**, it is used. Otherwise, the global default setting from the **DRPFrozenWindow** field on the **DRPConfiguration** table is used. **Note:** This field was added in Version 2016.2, Service Update 5.	Quantity	
EffectiveDRP Horizon	The length of the DRP horizon that is effective for this part. If a non-negative value is provided in **DRPHorizon**, it is used. Otherwise, the global default setting from the **DRPHorizon** field on the **DRPConfiguration** table is used. **Note:** This field was added in Version 2016.2, Service Update 5.	Quantity	
EffectiveDRP PlanningHorizon	The length of the DRP planning horizon that is effective for this part. If a non-negative value is provided in **DRPPlanningHorizon**, it is used. Otherwise, the global default setting from the **PlanningHorizon** field on the **DRPConfiguration** table is used. **Note:** This field was added in the Version 2016.2 Service Update 5.	Quantity	

Table 6.198: Calculated PartSolution (Solutions) fields

Field name	Description	Data type	Key
EffectiveMPSAuto FirmWindow	The MPS auto firm window value that is effective for this part. If a non-negative value is provided in **MPSAutoFirmWindow**, it is used. Otherwise, the default setting from the **AutoFirmWindow** field on the **MPSConfiguration.AutoFirmWindow** is used.	Quantity	
EffectiveMPS FrozenWindow	The length of the MPS frozen window that is effective for this part. If a non-negative value is provided in **MPSFrozenWindow**, it is used. Otherwise, the global default setting from the **FrozenWindow** field on the **MPSConfiguration** table is used.	Quantity	
EffectiveMPS Horizon	The length of the MPS planning horizon that is effective for this part. If a non-negative value is provided in **MPSHorizon**, it is used. Otherwise, the global default setting from the **Horizon** field on the **MPSConfiguration** table is used.	Quantity	

PartSource table

The **PartSource** table defines multiple sources of supply for a part.

The **BaseKey**, **Part**, and **Source** fields form the **PartSource** table's primary key. In many cases, **BaseKey** can be blank. When only one part source for a part exists, a blank **BaseKey** value is sufficient. Similarly, in cases where there is never more than one **PartSource** record for each supplier of a part, a blank **BaseKey** value is also valid.

Where there is more than one **PartSource** record per part, a BaseKey value must be created to ensure each **PartSource** record is unique.

For information on how RapidResponse handles the selection of multiple part sources, see "Planned orders" on page 1343.

Table 6.199: PartSource (Mfg) fields

Field name	Description	Data type	Key
Absolute PrePlanLimit	Maximum number of calendar days before its normal constraint allocation date that constraint can be planned or allocated to supplies using this part source. It is recommended that this value be set high enough so there is time to build the largest supply within its limit. If this field is set to a negative value then there is assumed to be no limit on how early RapidResponse may try to preplan constraints for supplies using this part source. If this field is set to zero then, depending on your RapidResponse installation, this either means no preplanning is allowed for supplies using this part source or there is no limit on the amount of preplanning allowed for supplies using this part source. However, the interpretation of zero values in this field can be configured as discussed in "Configuring AbsolutePrePlanLimit usage" on page 2206. **Default value:** - 1	Integer	
AllotmentOverride	A reference to the allotment override reserving component supply to dependent demands generated from supply using this part source. The reserved supply is allocated to these dependent demand(s) before it can be made available to dependent demands generated from supplies using a part source that does not reference the allotment override. **Referenced table:** AllotmentOverride (Nullable)	Reference	
BaseKey	The combination of Part (including Site), Source (including Supplier) and this field forms the primary key of this table. This field can remain blank if the Part and Source values are unique. **Default value:** A blank string.	String	Yes
BOMAlternate	A reference to the alternate BOM used by this part source. When Netting logic performs explosion calculations, only components that have **BillOfMaterial.Alternate** matched to either the value in this field or the first value in the **BOMAlternate** table (that is, common components) can potentially create dependent demands for supplies using this part source. For more information about alternate BOMs, see "Alternate BOM calculations" on page 1759. **Referenced table**: BOMAlternate	Reference	

Table 6.199: PartSource (Mfg) fields

Field name	Description	Data type	Key
CoProductYield	Indicates the percentage of a primary product's supply production that actually ends up as the primary product. The remainder is distributed between its co-products and by-products based on the QuantityPer values provided on the relevant BillOfMaterial records. This field respects the setting in the **OrderPolicy.YieldUsage** field, is applied after the Yield field, and is always considered by Netting calculations. If not using co-product and by-product logic in RapidResponse, this field should be set to 0 (indicates the field should be ignored). **Default Value:** 0 **Note**: If this yield is expected to vary over time, then the **TimePhasedYield** table should be used instead.	Quantity	
CRPFloatAfter	If using variable lead time based on work center capacity (**OrderPolicy.UseVarLeadTime** = "CRP"), this optional field indicates the amount of time to leave in the schedule after the final operation in the supply's routing completes. This can serve as a planning buffer to account for unexpected delays or interruptions incurred during work center operations. Expressed in Part.PlanningCalendars.TimeUnits.	Integer	
CRPFloatBefore	If using variable lead time based on work center capacity (**OrderPolicy.UseVarLeadTime** = "CRP"), this optional field indicates the amount of time to leave in the schedule before the first operation in the routing begins. This can serve as a planning buffer to account for unexpected delays in the receipt of component supplies. Expressed in Part.PlanningCalendars.TimeUnits.	Integer	

Table 6.199: PartSource (Mfg) fields

Field name	Description	Data type	Key
CTPIntervalsTo Expiry	This value is used to calculate the actual expiry date on scheduled receipts and planned orders. It should be expressed in intervals of the part's **PlanningCalendars.ExpiryCalendar**, and indicates the number of those intervals it takes supply from the part source to expire. The specific usage of this field in expiry date calculations depends on the part's setting in **PartType.ExpiryRule** as follows: • **Dependent**—Not used (expiry date is entirely determined from the part's component supplies). • **DependentStart**—Number of ExpiryCalendar intervals to add to the earliest expiry start date rolled up from a component supply (by default, that component's available date). • **DependentLimit**—Number of ExpiryCalendar intervals to add to the supply's DueDate (planned orders) or AvailableDate (scheduled receipts), and used only if that date is earlier than the earliest expiry date found on one of the part's component supplies). • **Ignore**—Not used (supply never expires). • **Self/SelfReset**—Number of ExpiryCalendar intervals to add to the supply's DueDate (planned orders) or AvailableDate (scheduled receipts). This value can be overridden at the scheduled receipt level if a date is provided in the **ScheduledReceipt.ExpiryDate** field. If the value in this field is 0 or negative, then the **IntervalsToExpiry** field is used instead. However, because **IntervalsToExpiry** is used in estimated expiry date calculations, which don't necessarily start from the same point as actual expiry date calculations (based on **ExpiryRule**), this should be done with caution. **Note:** This field was added in Version 2016.2, Service Update 5. **Default value**: 0	Integer	
DockToStockLead Time	The time required to move materials from the receiving dock to available inventory. The setting in this field increases the effective lead time for all types of supply; ensure it is set to 0 unless needed. It is measured using Part.PlanningCalendars.TimeUnits. **Default value**: 0 **NOTE**: If this value is expected to change over time, the TimePhasedPartSourcLeadTime table can be used instead.	Quantity	

Table 6.199: PartSource (Mfg) fields

Field name	Description	Data type	Key
EffectiveInDate	Defines the start of the period from which this part source record can be considered valid. This date along with the control setting in **PartSourceType.EffectivityRule** determines the first date from which supply can be planned from the part source (reported in the calculated **FirstEffectiveDate** field).	Date	
EffectiveOutDate	Defines the end of the period in which this part source record is valid. This date along with the control setting in **PartSourceType.EffectivityRule** determines the last date from which supply can be planned from the part source (reported in the calculated **LastEffectiveDate** field).	Date	
FixedLeadTime	Order release offset from due date. This represents a fixed amount of time to produce each order for the part from this source. **NOTE**: If this value is expected to change over time, the TimePhasedPartSourcLeadTime table can be used instead.	Quantity	
IntervalsToExpiry	This field is used internally by the Netting analytic in calculating an estimated expiry date on a potential planned order (this estimation is then used in determining if the part source can be used to supply a given demand). This value should be expressed in intervals of the part's **PlanningCalendars.ExpiryCalendar**, and indicates the number of those intervals it takes supply from the part source to expire. For parts with a **PartType.ExpiryRule** of "Dependent", this field should be set to account for the part's fastest expiring component. A value equal to or less than zero indicates that supplies using this part source should never expire. **Default value:** 0 Note: In previous versions, this field was also used in actual expiry date calculations. However, as of Version 2016.2, Service Update 5, the CTPIntervalsToExpiry field is used in actual expiry date calculations instead. However, if CTPIntervalsToExpiry is set to 0 or negative, then this field is still used in calculating the expiry date (as it was in previous versions).	Integer	
LaborCost	The standard labor cost associated with one unit of this supply (in SupplierUOM). Negative values are treated as zero. **Note:** The **PartSourceTimePhasedAttributes** table can be used to specify time-phased labor cost values. Values provided on that table override those on PartSource.	Money	

Table 6.199: PartSource (Mfg) fields

Field name	Description	Data type	Key
MaterialCost	Material cost associated with one unit of this supply. Used to calculate CostOfGoodsSold.MaterialCost. Also used to calculate CostRollUp.MaterialCost if PartSource.Type.CostRule control value is MaterialLaborOverheadCosts. Negative values are treated as zero. **Default value:** 0 **Note:** The **PartSourceTimePhasedAttributes** table can be used to specify time-phased material cost values. Values provided on that table override those on the **PartSource** table**.**	Money	
MaximumQty	The maximum order quantity (more than one planned order can be placed in a period). If **OrderPolicy.MaximumUsage** is set to either "Use" or "Average", then the quantity on any planned order generated from this part source will not exceed the value in this field (an exception is made on the last planned order in a period if the maximum number of orders per period has been reached). However, in cases where **MaximumUsage** is set to "CampaignPlanning", this field represents the maximum planned order quantity across all supply batches (orders) in a production campaign, and a new campaign must be started once that maximum is reached. In other words, the maximum number of batches allowed in a given production campaign is defined as `MaximumQty/MultipleQty` (and rounded up to the next integer where necessary). Note also that a global maximum on the number of batches in any campaign from any part source can be set as discussed in "Specify global batch limit" on page 1710. For all **MaximumUsage** settings other than those discussed above, the value in this field is ignored when generating planned orders. **Default value:** 0 (no maximum) **NOTE**: **SupplierUOM** applies to **MaximumQty**. CAUTION: Use of the **MaximumQty** setting typically results in more planned orders than would otherwise be generated. If the total demand quantity is large and the **MaximumQty** is set to a small number, then this can result in very large numbers of planned orders being generated which can potentially impact system performance. Note also that a global setting can be used to place a cap on the number of planned orders generated per part each day as discussed in "Limiting the number of planned orders" on page 2204.	Quantity	

Table 6.199: PartSource (Mfg) fields

Field name	Description	Data type	Key
MinimumQty	The minimum order quantity (more than one planned order can be placed in a period). If **OrderPolicy.MinimumUsage** is either "Use" or "RoundMult" then the quantity on any planned order generated from this part source will be greater than or equal to the value in this field (with this field being ignored when **MinimumUsage** is is set to "Ignore"). However, regardless of the **MinimumUsage** value, if the **OrderPolicy.MaximumUsage** option is set to "CampaignPlanning", then this field represents the minimum planned order quantity across all supply batches (orders) in a production campaign. This means a given campaign using this part source must continue planning batches until this minimum supply amount has been built. In other words, the minimum number of batches that make up a valid production campaign is defined as `MinimumQty/MultipleQty` (and rounded up to the next integer where necessary). Additionally, if **OrderPolicy.MaximumUsage** is set to "Kanban", than this field is not used in determining planned order quantities. **Note:** Depending on the setting in **PartSource.Type.ConstraintMinimumRule** this minimum value may also be applied when splitting supplies for constraint allocation or incremental availability. **Note: SupplierUOM** applies to **MinimumQty**.	Quantity	
MinimumShelfLife Threshold	This field can be used to override or extend the minimum shelf life requirements on dependent demands satisfied by orders from the part source. Values provided in this field should be expressed in **Part.PlanningCalendars. ExpiryCalendar** intervals. By default, the earliest expiry date on a planned order is taken from the dependent demand it is used to satisfy. However, if a positive value is provided in this field, then that number of intervals is added to the planned order due date. If the resulting date is later than the earliest expiry date on the dependent demand, it is reported in the **PlannedOrder.EarliestExpiryDate** field (otherwise, the **EarliestExpiryDate** from the **DependentDemand** record is used). **Default value:** -1	Integer	

Table 6.199: PartSource (Mfg) fields

Field name	Description	Data type	Key
MLSPreTarget Sequence	In multi-level search logic, this field can be used to specify an additional selection criterion that gets applied when distinguishing between eligible part sources of the same priority (where those eligible sources can satisfy the provide the supply on-time and the lowest level component supplies being used by each are of the same type). For example, this field might used to specify a preference between secondary part sources. A lower value in this field indicates a higher sort sequence or priority. Thus, if two part sources of the same priority are otherwise equivalent and eligible to provide a given supply, then the one with lower value in the field would be used. If those part sources had the same value in this field, then **PartSource.Target** field is next looked at to determine supply sourcing. **Note:** This field was added in Version 2016.2, Service Update 8.	Integer	
MultipleQty	The target lot size for planned orders. Generally, if **OrderPolicy.MultipleUsage** is set to "Use", then planned orders from the part source should be generated in multiples of this value (for other **MultipleUsage** settings, the value in this field is ignored). However, regardless of the **MultipleUsage** value, if the **OrderPolicy.MaximumUsage** option is set to "CampaignPlanning", then the value in this field represents the intended batch size and all planned orders from the part source are generated for exactly this quantity. Note that if this field is set to "0", then campaign planning is disabled even if **MaximumUsage** is set to "CampaignPlanning". Additionally, if **OrderPolicy.MaximumUsage** is set to "Kanban", than this field is not used in determining planned order quantities. **Note:** Depending on the setting in **PartSource.Type.ConstraintMultipleRule**, this multiple may also be applied when splitting supplies for constraint allocation or incremental availability. **Note: SupplierUOM** applies to **MultipleQty**.	Quantity	
OrderPolicy	Order policies for this part source. **Referenced table:** OrderPolicy	Reference	
OverheadCost	The standard overhead cost associated with one unit of this supply (in SupplierUOM). Negative values are treated as zero. **Note:** The **PartSourceTimePhasedAttributes** table can be used to specify time-phased overhead cost values. Values provided on that table override those on PartSource.	Money	

Table 6.199: PartSource (Mfg) fields

Field name	Description	Data type	Key
OverheadCost2	A second standard overhead cost associated with one unit of this supply. OverheadCost2 is used in the NewProcessCost calculation. Negative values are treated as zero. **Default value:** 0 **Note:** The **PartSourceTimePhasedAttributes** table can be used to specify time-phased overhead cost values. Values provided on that table override those on PartSource.	Money	
Part	The name of the part replenished by this part source. **Referenced table:** Part **Reference Syntax:** Part.Name, Part.Site	Reference	Yes
PlanningTimeFence	Used in determining the earliest a new order can be planned using this part source (based on the setting in the **OrderPolicy.PTFRule** field). This field should be expressed in either the part or source's time units (based on the setting in the **OrderPolicy.PTFUnit** field). **Default value**: 0	Quantity	

Table 6.199: PartSource (Mfg) fields

Field name	Description	Data type	Key
Pool	The pool associated with this part source. For parts that have inventory pooling logic enabled (the **MUEPoolNettingType.PoolRule** field is set to either "Net" or "Optional"), the referenced pool can influence the part source selection process. This is dependent on the **MUEPoolNettingType.PoolFlowToCommon** setting as follows: • When **PoolFlowToCommon** is either "NetOriginal", "Ignore", or "Forecast", planned orders can only be created on part sources where the **Pool** reference matches the pool being netted or is is Null. • When **PoolFlowCommon** is "NetCommon", planned orders can only be created on part sources where the **Pool** reference matches the "common" pool, or is Null. Note that this means planned orders cannot be created on part sources where the **Pool** reference is a match for the pool being netted. Once the part source is chosen in consideration of pool, new planned orders are created on either the matching supply pool or common pool, and dependent demands generated on components inherit their pools from the parent supplies. Thus, if pooling is enabled on an end-item assembly, part source selection for the assembly can be pool-based and that pool information propagated down to its components. When pooling is disabled on an end-item assembly and this field is populated, supplies are still planned in the common pool (as determined from **PlanningCalendars.CommonPool**) and the part source(s) that can be used for those supplies are not dependent on the referenced **PartSource.Pool** values. However, if pooling is enabled on a lower-level component, then the Pool referenced from that assembly can be injected onto the dependent demands and hence planned supplies for those components. **Referenced table:**Pool (Nullable) **NOTE**: This field was added in Version 2016.2, Service Update 19. For more information, see "Pools and part sources" on page 1750.	Reference	

Table 6.199: PartSource (Mfg) fields

Field name	Description	Data type	Key
PrePlanLimit	The maximum number of Source.LeadTimeUnits to try to plan orders (when the current period has insufficient constraint(s)) before trying to plan orders through lower priority part sources. Other part sources at the same priority will be used in the current period if they are available. Also, if none of the part sources can satisfy the demand for the current period, respecting pre-plan limit, then test periods before the pre-plan limits. This field is dependent upon its value: • **<0**—use this source in earlier periods until it has no more earlier constraint available (PTF, Constraint.DataDate, FirstEffectiveDate) before trying lower priority part sources in the current period. All negative values are treated identically. • **0**—test other sources in the current period before trying this source in earlier periods (default is 0). • **>0**—test part sources at the same priority as this source in the current period, then test this source (then others at the same priority, respecting their PrePlanLimit) in earlier periods, up to and including the period containing the initial calculated ship date less the value of the Source.LeadTimeUnits field.	Integer	
Priority	A priority value to use when selecting a PartSource to supply a given part requirement (used when there are multiple active PartSources can either provide the supply on-time or else equally late). The interpretation of this value is controlled by the **SourceRule.PriorityRule** field (defines whether higher or lower values are assumed to indicate a higher effective priority).	Quantity	
ProductionRecurrence	A reference to the production recurrence associated with this PartSource record. **Referenced table:** ProductionRecurrence	Reference	
ProductionGroup	A reference to the production group associated with this PartSource record. **Referenced table:** ProductionGroup	Reference	
ProductionWheel	A reference to the production wheel associated with this PartSource record. **Referenced table:** ProductionWheel	Reference	

Table 6.199: PartSource (Mfg) fields

Field name	Description	Data type	Key
Routing	The standard routing for supplies using this part source. This field is used by the Capacity Requirements Planning analytic. This field must contain a value (it can be set to "None" if it is not being used. **Referenced table:** Routing **Reference Syntax:** Routing.Id	Reference	
SafetyLeadTime	Number of days to offset the demand due date when determining when supply should be planned to cover that demand. This is intended to protect against fluctuations in supply and demand and will impact planned order due dates as well as EffLeadTime and CumLeadTime calculations. This value should be expressed in either the part's **PlanningCalendars.TimeUnits** calendar or the Everyday/Gregorian calendar as determined by the part's **PartType.SafetyLeadTimeCalendarRule** setting. Note that usage of this field depends on the setting in the **PartType.UseSafetyLeadTime** field, with additional **PartType** settings available to specify how safety lead time is applied for specific types of demands. **Default value**: 0 **Note:** SafetyLeadTime is ignored and not used to offset due dates for safety stock demands.	Integer	
SecondaryPriority	If the part's **SourceRule.AllotmentRule** is set to "ProportionalLotSize" or "OngoingToDate", this field is used to chose between eligible sources of the same **Priority** that also have the same **Target** value or the same **Target** value and calculated quota rating. This value is also used in multi-level search logic in cases where two eligible part sources are still considered equal after evaluating their **Target** values. The interpretation of this value is controlled by the **SourceRule.PriorityRule** setting (defines whether higher or lower values are assumed to indicate a higher secondary priority). **Note:** This field was added in Version 2016.2, Service Update 6.	Quantity	
ShippingCost	The standard cost associated with shipping using this part source. Negative values are treated as zero. This field is in the **Solutions** namespace. **Note:** This field was added in the Version 2016.2, Service Update 5.	Money	

Table 6.199: PartSource (Mfg) fields

Field name	Description	Data type	Key
Source	Provides information about the source. For example: name, phone, and email. **Referenced table:** Source **Reference Syntax:** Source.Id, Source,Supplier.Id	Reference	Yes
SupplierPart	Supplier's part number (used for reporting if the part source is not a Transfer). If the part has only one part source, leave this field empty. If the part has more than one part source, specify the supplier's part number.	String	
SupplierUOM	The units used for ordering from this source. Dependent demands are created using this unit of measure (UOM). SupplierUOM applies to all unit quantity fields in PartSource. These are: • MaximumQty • MinimumQty • MultipleQty • ToDateQuantity • Yield (only if the OrderPolicy.YieldUsage control value is ScrapPiece)	String (Enum)	
TaktTime	The number of time units (typically, work days) in between consecutive planned orders when the required quantity for the part exceeds the value in **MaximumQty**. The time unit is set by the value in **Part.PlanningCalendars.TimeUnits**. If this field is < 0, then planned orders are spread back in time starting from the supply's original due date. If this field is > 0, then planned orders are spread ahead in time starting from the supply's original due date. If the spread planned orders reach PTFDate before the required quantity is created, then multiple planned orders are created on PTFDate. If this field is set to 0, then multiple planned orders to satisfy a demand for the part can be created on the same date. For more information, see "Spreading planned orders with Takt Time" on page 1376. **Default value**: 0 **Note:** If a given part source uses Takt Time (that is, TaktTime <> 0), then the part source is treated as unconstrained regardless of whether or not any constraints are assigned to the part source.	Integer	

Table 6.199: PartSource (Mfg) fields

Field name	Description	Data type	Key
Target	Target allotment value to use for this part source when there are multiple active part sources (of the same priority) eligible to satisfy planned requirements for the part. This value is used to determine the percentage split of planned requirements among the active part sources. Depending on the setting in the **SourceRule.AllotmentRule** field, this split among sources is either made proportionally between sources for each requirement or on ongoing basis with each requirement meant to be satisfied by only one source whenever possible. If all active part sources have their Target set to 0, this indicates demands should be evenly split across the eligible sources. **Default value:** 0	Quantity	
ToDateQty	The quantity that has been allocated to this part source to date. It's used as the initial value for ongoing allotments. **Note: SupplierUOM** applies to **ToDateQty**.	Quantity	
TransferPart	Part to be supplied (only used for Transfer sourcing, includes site.) Typically set to the part itself for Make and Buy part sources. **Referenced table:** Part **Reference Syntax:** TransferPart.Name, TransferPart.Site	Reference	
Type	A value that is associated with processing rules that defines how the sourcing data is interpreted. **Referenced table:** PartSourceType	Reference	
UnitCost	The cost of one unit (in terms of SupplierUOM) of this part from this part source. This cost is assumed to include material, labor, and overhead costs combined. It is therefore similar to Part.StdUnitCost. For a part's primary part source, this field will typically equal Part.StdUnitCost, with appropriate UOM conversion.	Money	
VarLeadTime	The portion of lead time dependent upon order quantity (in units of SupplierUOM). If **OrderPolicy.UseVarLeadTime** is set to "Y", the value in this field is then multiplied by the order quantity (**PlannedOrder.Quantity** or **ScheduledReceipt.Quantity)** to determine the variable portion of lead time. Otherwise, this field is ignored. **Note:** VarLeadTime is also ignored if **PartSourceType.ConstraintDateRule** is set to either "DuringLeadTime", "Start", or "StartExtend".	Quantity	

Table 6.199: PartSource (Mfg) fields

Field name	Description	Data type	Key
Yield	Factor to reduce supply quantities to account for scrap. This value is affected by the **OrderPolicy.YieldUsage** control value. If this factor is expected to vary over time, then the **TimePhasedYield** table should be used to specify yield values for the part source. **Note: SupplierUOM** applies to **Yield** (only if the **OrderPolicy.YieldUsage** control value is ScrapPiece).	Quantity	

PartSource table – calculated and set fields

The following describes the calculated and set fields in the PartSource table. For an introduction to this table, and descriptions of its input fields, see "PartSource table" on page 459.

Table 6.200: Calculated PartSource (Mfg) fields

Field name	Description	Data type	Key
EffFixedLeadTime	Fixed lead time (based on FixedLeadTime and OrderPolicy values.) **NOTE**: If using time-phased fixed lead times, then the lead time effective at the latter of the part's **RunDate** or **PartSource.FirstEffectiveDate** is used.	Quantity	
EffLeadTime	The total lead time for this part source (sum of all lead time components defined on the part and part source). This includes effective safety, fixed, and variable lead times as well as lead time adjustments. For part sources where the **Type.TransitRule** is set to "Cumulative", this also includes pre-ship lead time, transit time, and dock-to-stock lead time. **Note:** Fixed and variable lead times are ignored when calculating lead time for transfer sources (lead time calculations start from the built date). **Note:** If using time-phased lead time (for fixed, dock-to-stock, transit, or pre-ship lead times). then the lead times effective at the latter of the part's **RunDate** or **PartSource.FirstEffectiveDate** are used. **Note:** If using time-phased safety lead time for a part, any effective and applicable values defined in the **SafetyLeadTimeProfileDetail** table are ignored when calculating the value returned by this field. If populated, the **Part.SafetyLeadTime** field value is used instead.	Quantity	

Table 6.200: Calculated PartSource (Mfg) fields

Field name	Description	Data type	Key
EffUnitCost	The unit cost of one unit of this part source (reported in terms of stock units). The calculation used to populate this field depends on the setting in the **PartSourceType.CostRule** field as follows: • If set to "MaterialLaborOverheadCosts" then calculated based on the material, labor and overhead values on either the applicable **PartSourceTimePhasedAttributes** record (if one exists) or the **PartSource** record. • Otherwise if set to "UnitCost" then derived from the **UnitCost** value on the **PartSource** record. • And if the applicable calculation returns a value less than or equal to zero (<= o), then derived from the **Part.StdUnitCost** value. Currency conversions on this field use the **FirstEffectiveDate** field's conversion rate.	Money	
EffVarLeadTime	Variable lead time (based on VarLeadTime and OrderPolicy rules).	Quantity	
EffYield	Effective yield on this part source. Calculated by combining (multiplying) the **Yield** and **CoProductYield** values (and respecting the **OrderPolicy.YieldUsage** value). If **OrderPolicy.YieldUsage** is set to 'ScrapPiece' this field reports -Yield, and the net quantity added to inventory is Quantity + EffYield. If **OrderPolicy.YieldUsage** is set to anything other than 'ScrapPiece' this field reports a value between 0 and 1, and the net quantity added to inventory is Quantity * EffYield. **Note**: If time-phased yield logic is applicable, the **Yield** and **CoProductYield** values used are taken from the **TimePhasedYield** table. For a given part source, the **TimePhasedYield** record that is effective on the latter of **PartSource.EffectiveInDate** or **Part.RunDate** is used.	Quantity	
FirstEffectiveDate	Date when this PartSource record becomes effective (undefined if never effective). Planned orders from the part source cannot be earlier than this date (or later than **LastEffectiveDate**). If a demand falls outside of the effective window for all potential part sources, then it can either be shifted into effectivity or left unsatisfied (based on the part's **SourceRule.SourceEffectivityWindow** setting).	Date	

Table 6.200: Calculated PartSource (Mfg) fields

Field name	Description	Data type	Key
IsRecursive	Set to Y when this PartSource record is involved in a recursive data structure. For example, this might occur when a part is a component of itself. Similarly, this might occur if there is a part at two different sites and each has a transfer part source meant to transfer supply from the other part and site. Valid values are: • Y • N **Default value:** N **Note**: For more information about recursive data, see "Recursive data" on page 1423.	Boolean	
LastEffectiveDate	Last date when this PartSource record remains effective (undefined if never effective). Planned orders from the part source cannot be later than this date (or earlier than **FirstEffectiveDate**). If a demand falls outside of the effective window for all potential part sources, then it can either be shifted into effectivity or left unsatisfied (based on the part's **SourceRule.SourceEffectivityWindow** setting).	Date	
LeadTimeDate	The lead time date for this part source. This date is calculated starting from the run date (**Part.PlanningCalendars.RunDate.FirstDate)** and adding all lead time components (either inclusive or cumulative) while respecting the relevant planning calendars. This field is useful when looking for demand and supply due within a part source's lead time. For more information about lead time, see "Lead time calculations" on page 1307.	Date	
PTFDate	The date of the planning time fence calculated based on the run date, **PlanningTimeFence**, and the setting in the **OrderPolicy.PTFRule** field. When **OrderPolicy.OrderGenerationRule** is set to "AfterPTFDate", planned orders from the part source can only be generated after this date. **NOTE**: If time-phased lead times are used, then the lead times effective at the latter of the part's **RunDate** or **PartSource.FirstEffectiveDate** are used.	Date	
SourceKanban	The SourceKanban selected for this part source. If this part source has no SourceKanbans, then this reference can be null. **Referenced table**: SourceKanban	Reference	

Table 6.200: Calculated PartSource (Mfg) fields

Field name	Description	Data type	Key
CTPPlannedOrders	Set of records on calculated table that contain a reference to a CTPPlannedOrder using this PartSource.	Set	
MEIOLeadTimes	Set of MEIOLeadTime records that contain stochastic lead time parameters for this part source.	Set	
MEIOParts	Set of SafetyStockPart records containing safety stock parameters for parts from this part source.	Set	
NewTransfer Allocations	Set of NewTransferAllocation records (dependent demands) arising from transfer Scheduled Receipts through this part source.	Set	
PlannedOrders	Set of records on calculated table that contain a reference to a PlannedOrder using this PartSource.	Set	
PlannedTransfer Allocations	Set of dependent demands arising from PlannedTransferAllocation records through this part source.	Set	
ScheduledReceipts	Set of records that contain a reference to a ScheduledReceipt using this PartSource.	Set	
SourceKanbans	Set of SourceKanban records for this part source.	Set	
SupplyAllocations	Set of manual (user specified) SupplyAllocation records that define allocations of supply to demand made where the supply uses this part source.	Set	
TimePhased Attributes	Set of PartSourceTimePhasedAttributes records for this part source.	Set	
TimePhased LeadTimes	Set of PartSourceTimePhasedLeadTime records for this part source.	Set	
TimePhased Yields	Set of TimePhasedYield records for this part source.	Set	

PartSourceTimePhasedAttributes table

The PartSourceTimePhasedAttributes table is used to define time-phased cost values on part sources. Each record contains a reference to the PartSource record to which the cost values apply, and an effective date indicating the date from which the values are effective. If a given part source has an effective record in this table at a particular date, and the sum of all cost values in that record are greater

than zero, then the cost values from that record override the corresponding values on the part source. Otherwise, the cost values from the PartSource record are used.

This table allows for time-phased costing by part source without the need to create and maintain multiple PartSource records. This can result in improved performance of certain RapidResponse analytics and reduces the effort in trying to match scheduled receipts to the appropriate part source and cost values.

Table 6.201: PartSourceTimePhasedAttributes (Mfg) fields

Field name	Description	Data type	Key
EffectiveDate	The date when this set of attributes becomes effective. Time-phased attributes are considered effective until the next record with a later EffectiveDate is found for a given part source. When determining the effective set of attributes for a given supply, the **DueDate** (planned orders) or **ReschedDate** (scheduled receipts) are compared against this value.	Date	
Id	An identifier for this set of time-phased attributes. The combination of this value and the PartSource reference are used to uniquely identify this record.	String	Yes
LaborCost	The standard labor cost associated with one unit of supply from this source (in SupplierUOM). Negative values are treated as zero.	Money	
MaterialCost	The material cost associated with one unit of supply from this source (in SupplierUOM). Negative values are treated as zero.	Money	
OverheadCost	The standard overhead cost associated with one unit of supply from this source (in SupplierUOM). Negative values are treated as zero.	Money	
OverheadCost2	A second standard overhead cost associated with one unit of supply from this source. This field is used in the NewProcessCost calculation. Negative values are treated as zero.	Money	
PartSource	A reference to the part source this set of time phased attributes applies to. **Referenced table:** PartSource **Reference Syntax:** PartSource.Part.Site, PartSource.Part.Name, PartSource.Source.Id, PartSource.Source.Supplier.Id, PartSource.BaseKey	Reference	Yes

PartSupplier table

This table identifies each unique part and supplier combination used in historical data.

Table 6.202: PartSupplier (Mfg) fields

Field name	Description	Data type	Key
Part	The part associated with the historical supply series. **Referenced table**: Part **Reference Syntax**: Part.Name, Part.Site	Reference	Yes
Supplier	The supplier associated with the historical supply series. **Referenced table**: Supplier **Reference Syntax**: Supplier	Reference	Yes
SupplierUOM	The unit of measure associated with this PartSupplier record. **Referenced table:**UnitOfMeasure **Note**: This field was added in Version 2016.2, Service Update 12.	Reference	
ToleranceProfile	The name of the tolerance profile used for this part and supplier combination. Tolerance profiles define the calendar used in calculating the baseline historical supplier series as well as the calendar used when calculating tolerance zones for measuring acceptable levels of change in forecasts. **Referenced table**: ToleranceProfile (this reference is nullable in new installations of RapidResponse 10.1 and later).	Reference	

PartSupplier table – calculated and set fields

The following describes the calculated and set fields in the PartSupplier table. For an introduction to this table, and descriptions of its input fields, see "PartSupplier table" on page 477.

Table 6.203: Calculated PartSupplier (Mfg) fields

Field name	Description	Data type	Key
HistoricalSupply Headers	The set of historical supply series' associated with this part and customer combination.	Set	

PartUOMConversion table

The **PartUOMConversion** table is used to store part-specific unit of measure conversion rates. Records stored in this table are used to calculate forecast item quantities when generating a statistical forecast. It allows a part to be calculated using a factor that is specific to that part, instead of the **UnitOfMeasure.BaseConversion** that is specified for a **UnitofMeasure**. Therefore, if a part has a unit of measure conversion record in the **PartUOMConversion** table, the **UnitOfMeasure.BaseConversion** is ignored. The **PartUOMConversion** table should be used if the **Part.UnitOfMeasure** has a different base unit value than the one that is given in **UnitOfMeasure.BaseConversion**. The part-specific unit of

measure conversion factor needs to be entered to ensure that the quantities are correctly converted to a different unit of measure. For more information, see "Define unit of measure" on page 2027.

Quantities in the following tables are calculated using **PartUOMConversion**:

- **ForecastItemParametersActual**
- **StatisticalForecast**
- **StatisticalForecastDetail**
- **StatisticalForecastDisaggregationRate**

Notes:

- To successfully use the **Unit of Measure** control in any of the workbooks, it's necessary to assign a **ForecastItemParameters.UnitofMeasure** as well as **PartUOMConversion** even if the forecast item is reported in the same unit of measure as their part-customers.
- The capability to use the **PartUOMConversion** table to define a part-specific unit of measure conversion rate for calculating of the statistical forecast was added in Version 2016.2, Service Update 12. Prior to this update, the table was intended to store part-specific unit of measure conversion rates only for reporting purposes.

Table 6.204: PartUOMConversion (Mfg) fields

Field name	Description	Data type	Key
Factor	The conversion factor used to convert values from **Part.UnitOfMeasure** to **UnitOfMeasure**. The following formula is used to convert a quantity from **Part.UnitOfMeasure** to **UnitOfMeasure**: Quantity * PartUOMConversion.Factor	Quantity	
Part	A reference to the part and site whose unit of measure this conversion factor applies to. **Referenced table:** Part **Reference Syntax:** Part.Name, Part.Site	Reference	Yes
UnitOfMeasure	The unit of measure to which the factor in this table is used in converting to. **Referenced table:** UnitOfMeasure	Reference	Yes

PartValidation table

The **PartValidation** table is used to record notes about parts during input validation.

This table was added in Version 2016.2 Service Update 9, and modified in Version 2016.2 Service Update 11.

Table 6.205: PartValidation (Validation) fields

Field name	Description	Data type	Key
CommentsByPart	Additional information about the part.	String	
CommentsForDemand	Additional information about known demand issues for the part.	String	
CommentsForOnHand	Additional information about known on hand issues for the part.	String	
CommentsForSupply	Additional information about known supply issues for the part.	String	
Flagged	Whether the part has been flagged.	Boolean	
KnownIssueByPart	Whether the part has known issues recorded.	Boolean	
KnownIssueForDemand	Whether the part has known issues for demand recorded.	Boolean	
KnownIssueForOnHand	Whether the part has known issues for on hand recorded.	Boolean	
KnownIssueForSupply	Whether the part has known issues for supply recorded.	Boolean	
Notes	Notes about the part and its validation operations.	Note	
Part	The part being recorded. **Referenced table:** Mfg::Part	Reference	Yes

PenaltySchedule table

The **PenaltySchedule** table contains string values identifying the different penalty schedules that can be used in RapidResponse. Both the **Project** and **Task** tables reference this table to specify the penalty schedule, if any, associated with a given project or task.

Each record in this table is also associated with a set of referencing records in both the **PenaltyScheduleByDate** and **PenaltyScheduleByInterval** tables. These tables define the one-time and recurring costs that are associated with a given penalty schedule.

This table's records can be edited using the **Penalty Schedules** worksheet in the **Project Master Data** workbook included with RapidResponse.

Table 6.206: PenaltySchedule (ProjMgmt) fields

Field name	Description	Data type	Key
Description	A description of this penalty schedule.	String	
Name	A unique name for this penalty schedule. This value can be referenced by both the **Project.PenaltySchedule** and **Task.PenaltySchedule** fields to set the penalty schedule associated with a given project or task.	String	Yes
Site	The site associated with this penalty schedule. Referenced table: Site	Reference	Yes

PenaltySchedule table – calculated and set fields

The following describes the calculated and set fields in the **PenaltySchedule** table. For an introduction to this table, and descriptions of its input fields, see "PenaltySchedule table" on page 480.

Table 6.207: Calculated PenaltySchedule (ProjMgmt) fields

Field name	Description	Data type	Key
PenaltiesByDate	Set of date based penalty costs associated with this penalty schedule.	Set	
PenaltiesBy Interval	Set of interval based penalty costs associated with this penalty schedule.	Set	
Projects	Set of projects that use this penalty schedule.	Set	
Tasks	Set of tasks that use this penalty schedule.	Set	

PenaltyScheduleByDate table

The **PenaltyScheduleByDate** table holds date effective records used to define the one-time and recurring penalty costs for a specified penalty schedule and the projects and/or tasks that use that penalty schedule. The specified penalty costs can then be applied both to projects that have a **ProjectType.PenaltyRule** value of "Date" as well as tasks that have a **TaskType.PenaltyRule** value of "Date".

For example, this table can be used to set up a penalty schedule that applies a one-time penalty cost if a project is not finished by its penalty date and then applies a recurring penalty cost for each workday after that until it finishes.

This table's records can be edited using the **Penalties by Effective Date** worksheet in the **Project Master Data** workbook included with RapidResponse. For more information about how this table is used, see "Date-based penalty schedules" on page 2192.

Table 6.208: PenaltyScheduleByDate (ProjMgmt) fields

Field name	Description	Data type	Key
EffectiveDate	Sets the first date on which the penalty costs defined on this record can be applied to referencing projects or tasks. The costs are effective until the next EffectiveDate associated with the referenced penalty schedule. If there are multiple effective records between a project or task's penalty date and finish date, then effective penalty costs are used as defined by the setting in the **AccumulationRule** field on either the **ProjectType** or **TaskType** table.	Date	
Id		String	Yes
OneTimeCost	A one-time penalty cost applied to be applied to projects or task's that have a **CalcFinishDate** later than their **PenaltyDate**.	Money	
PerIntervalCost	A recurring penalty cost. Applied for each effective date between a project or task's **PenaltyDate** and **CalcFinishDate** that belongs to the penalty calendar associated with the project type or task type. For example, penalty costs might be applied on each workday or each weekly interval.	Money	
Schedule	A reference to the named penalty schedule these penalty costs apply to. **Referenced table**: PenaltySchedule	Reference	Yes

PenaltyScheduleByInterval table

The **PenaltyScheduleByInterval** table holds interval-based records, expressed in terms of penalty calendar intervals, used to define the one-time and recurring penalty costs for a specified penalty schedule and the projects and/or tasks that use that penalty schedule. The specified penalty costs can then be applied both to projects that have a **ProjectType.PenaltyRule** value of "Interval" as well as tasks that have a **TaskType.PenaltyRule** value of "Interval".

For example, assuming a weekly calendar, this table can be used to set up a penalty schedule that applies one set of weekly penalty costs for projects that are less than four weeks past their penalty date without finishing, and then applies another set of weekly penalty costs for projects that are more than four weeks past their penalty date without finishing.

This table's records can be edited using the **Penalties by Interval** worksheet in the **Project Master Data** workbook included with RapidResponse. For more information about how this table is used, see "Interval-based penalty schedules" on page 2194.

Table 6.209: PenaltyScheduleByInterval (ProjMgmt) fields

Field name	Description	Data type	Key
Id	A unique string identifier for this record.	String	Yes
Interval	The number of penalty calendar periods after the project or task's **PenaltyDate** at which the costs in this record become effective. For example, if using a weekly penalty calendar, a value of 2 in this field indicates that the costs defined in this record are effective starting from the second week after the penalty date and remain applicable until the next effective record. If there are multiple effective Interval values between a project or task's penalty date and finish date, then effective penalty costs are used as defined by the setting in the **AccumulationRule** field on either the **ProjectType** or **TaskType** table.	Integer	
OneTimeCost	A one- time penalty cost to be applied to projects or task's that have a **CalcFinishDate** later than their **PenaltyDate**.	Money	
PerIntervalCost	A recurring penalty cost. Applied for each effective date between a project or task's **PenaltyDate** and **CalcFinishDate** that belongs to the penalty calendar associated with the project type or task type. For example, penalty costs might be applied on each workday or each weekly interval.	Money	
Schedule	A reference to the named penalty schedule these penalty costs apply to. **Referenced table**: PenaltySchedule	Reference	Yes

PlannerCode table

The **PlannerCode** table contains a list of valid planner codes. The planner code is meant to identify a person or job responsibility for making planning decisions for the part. This table and the PlannerCode field in the **Part** table have no algorithmic use.

This table's **Site** field is optional, and a system or data administrator can choose whether it uniquely identifies records in the table, or is ignored in queries, and not shown in insert definitions, dialog boxes, or the Data Sources and Mapping window.

Table 6.210: PlannerCode (Mfg) fields

Field name	Description	Data type	Key
Description	A description of this planner code.	String	
Site	The site associated with this planner code. This field is optional. **Referenced table:** Core::Site	Reference	Yes
UserId	The user responsible for this buyer code. This field is in the **Solutions** namespace.	String	
Value	A unique identifier associated with this planner code.	String	Yes

For more information about making the **Site** field optional, see "Modifying table and field properties" in the *RapidResponse Data Integration Guide*.

PlannerCode table – calculated and set fields

The following describes the calculated and set fields in the **PlannerCode** table. For an introduction to this table, and descriptions of its input fields, see "PlannerCode table" on page 483.

Table 6.211: Calculated PlannerCode (Mfg) fields

Field name	Description	Data type	Key
CustomerService Representatives	Set of **Customer** records that use this record to identify a customer service rep.	Set	
DemandPlanner Codes	Set of **PartSolution** records that use this record to identify the demand planner responsible for a part.	Set	
InventoryPlanner Codes	Set of **PartSolution** records that use this record to identify the inventory planner responsible for a part.	Set	
MasterScheduler Codes	Set of **PartSolution** records that use this record to identify the master scheduler responsible for a part.	Set	
Parts	Set of parts associated with this planner code.	Set	

PointsCurve table

The **PointsCurve** table holds named efficiency curves which are sets of curve points defining varying rates of resource efficiency during the course of a task. Typically, these might be used to define tasks on which resources ramp up to full efficiency as the task progresses. For example, resources assigned to a

given task might be 20% efficient at one stage of the task, 60% efficient at another stage, and 100% efficient at all subsequent stages. These efficiency rates then impact the tasks expected and calculated duration.

Each curve defined in this table is used by any entries in the Task table that reference it through their **PointsCurve** field and that have a **TaskType.EfficiencyCurveRule** of "PointsCurve". The individual point values that make up each curve are defined in the **CurvePoint** table which also has a reference to this table.

This table's records can be edited using the **Manage Efficiency Curves** worksheet in the **Project Master Data** workbook included with RapidResponse.

Table 6.212: PointsCurve (ProjMgmt) fields

Field name	Description	Data type	Key
Description	A description of this points curve.	String	
Name	A unique name for this efficiency curve. This value is referenced both by all CurvePoint records that define this curve, as well as by all Tasks that use this curve to define resource efficiency.	String	Yes

PointsCurve table – calculated and set fields

The following describes the calculated and set fields in the PointsCurve table. For an introduction to this table, and descriptions of its input fields, see "PointsCurve table" on page 484.

Table 6.213: Calculated PointsCurve (ProjMgmt) fields

Field name	Description	Data type	Key
CurvePoints	Set of CurvePoint records that reference this PointsCurve value.	Set	
Tasks	Set of Tasks records that reference this PointsCurve value.	Set	

PointsProfile table

This table contains the names of all profiles (curves) used in generating statistical forecast for new-product-introduction (NPI) and end-of-life (EOL) items.

The PointsProfile table supports Sales and Operations Planning in RapidResponse. Values in this table are maintained through the **S&OP Forecast Item Management** workbook in RapidResponse. For more information about profiles for NPI and EOL items, see the *RapidResponse Applications Guide*.

Table 6.214: PointsProfile (Mfg) fields

Field name	Description	Data type	Key
Description	A description of this profile.	String	
Name	A unique identifier (name) for this profile.	String	Yes

PointsProfile table – calculated and set fields

The following describes the calculated and set fields in the PointsProfile table. For an introduction to this table, and descriptions of its input fields, see "PointsProfile table" on page 485.

Table 6.215: Calculated PointsProfile (Mfg) fields

Field name	Description	Data type	Key
ForecastItem ParametersForecast Profiles	Set of forecast items this profile is applied to.	Set	
ProfilePoints	Set of forecast item parameters associated with this PointsProfile record.	Set	
Statistical Forecast Overrides	Set of part customers associated with this PointsProfile record.	Set	

Pool table

A pool represents a set of supplies and demands that are segregated from other supplies and demands for the same part. Sometimes supplies for one customer are separately managed from supplies for other customers. In such a situation, inventory pooling is used. For more information about pools, see "Understanding pools" on page 1745.

The **Pool** table supports contains the names of each inventory pool used in netting. Pools are synonymous with a contract, project, contract group or project group.

The **Pool** table must be included in the data extract even if the Pool capability is not enabled, and there must be at least one entry in this table. The first pool name loaded into the **Pool** table (and the only pool entry for implementations where Pool is not enabled) is called Unpooled and is the default pool.

When a part is not netted by pool (the **Part.MuePoolNettingType.PoolRule** control value is **Ignore**), all supplies and demands for the part are treated as being in the **Unpooled** pool.

When the value of the **Part.MuePoolNettingType.PoolRule** control value is **Net**, the **Unpooled** pool might also be used as a distinct pool.

Table 6.216: Pool (Mfg) fields

Field name	Description	Data type	Key
Description	Additional information about the pool. **Default value**: blank string	String	
Value	The name of the pool. The same pool name can be used for different parts. **Note:** The first pool name loaded into this table is called 'Unpooled'. This is the default pool. **Default value**: Unpooled	String	Yes

PoolMap table

The **PoolMap** table specifies rules to allocate demand to supplies on a PartType basis.

Table 6.217: PoolMap (Mfg) fields

Field name	Description	Data type	Key
DemandPool	The DemandPool that is mapped to the SupplyPool for processing. **Referenced table:** Pool **Reference Syntax:** DemandPool.Value	Reference	
PartType	The PartType this relationship relates to. **Referenced table:** PartType	Reference	
SupplyPool	The Supply Pool whose potential customers are being defined. **Referenced table:** Pool **Reference Syntax:** SupplyPool.Value	Reference	

PoolMapOverride table

The **PoolMapOverride** table specifies rules to allocate demand to supplies on a part basis overriding any mapping specified by the PoolMap table.

Table 6.218: PoolMapOverride (Mfg) fields

Field name	Description	Data type	Key
DemandPool	The DemandPool that is mapped to the SupplyPool for processing. **Referenced table:** Pool **Reference Syntax:** DemandPool.Value	Reference	
Part	The Part that this relationship related to. **Referenced table:** Part **Reference Syntax:** Part.Name, Part.Site	Reference	
SupplyPool	The Supply Pool whose potential customers are being defined. **Referenced table:** Pool **Reference Syntax:** SupplyPool.Value	Reference	

Predecessor table

The **Predecessor** table identifies dependencies between pairs of project tasks. This table has two references to the **Task** table. The **Predecessor** reference identifies a "predecessor" task that typically must come before another task, and the **Task** reference identifies a "successor" task that typically comes after the predecessor task.

This table also be used to define how these task dependencies affect each other's start or finish dates. In projects where **ProjectType.ScheduleRule** is 'FromStart' this table can be used to specify how a successor task's start or finish date is constrained by the calculated start or finish date on a predecessor task. Similarly, in projects where **ProjectType.ScheduleRule** is 'FromFinish', this table can be used to specify how a predecessor task's start or finish date is constrained by the calculated start or finish on a successor task.

If using Task-based worksheets automatically configured for project management, such as in the **Project Plan** workbook included with RapidResponse, values can be added to this table through the **Predecessors** tab of the **Task Information** dialog box

Table 6.219: Predecessor (ProjMgmt) fields

Field name	Description	Data type	Key
Description	A description of this task dependency.	String	
Offset	Number of days to offset either the predecessor or successor task's calculated start or finish date, in order to calculate when the other can potentially start or finish. The usage of the offset value is determined both by the **Rule** setting on this table, and the project's **Type.ScheduleRule** setting as follows: • If **Project.Type.ScheduleRule** is 'FromStart' and **Rule** is 'FinishToStart' or 'FinishToFinish', this value is added to the predecessor task's calculated finish date. • If **Project.Type.ScheduleRule** is 'FromStart' and **Rule** is 'StartToFinish' or 'StartToStart', the this value is added to the predecessor task's calculated start date. • If **Project.Type.ScheduleRule** is 'FromFinish' and **Rule** is 'FinishToFinish' or 'StartToFinish', this value is subtracted from the successor task's calculated finish date. • If **Project.Type.ScheduleRule** is 'FromFinish' and **Rule** is 'FinishToStart' or 'StartToStart', this value is subtracted from the successor task's calculated start date. **Note:** This value is ignored if **Rule** is set 'None'.	Quantity	
Predecessor	A reference to the predecessor task. This is the task that comes first (before the successor) in the task relationship defined by this record. **Referenced table**: Task	Reference	Yes

Table 6.219: Predecessor (ProjMgmt) fields

Field name	Description	Data type	Key
Rule	Specifies how the task dependency defined by this record is used when calculating task start and finish dates (depends on the projects' **Type.ScheduleRule** setting). For example, should a task be constrained from starting until its predecessor task has finished. Valid values are: • **FinishToFinish**—if **Project.Type.Schedule Rule** is 'FromStart', then the earliest the successor task can finish is the predecessor task's calculated finish date plus any applicable offset. Else, if **Project.Type.Schedule Rule** is 'FromFinish', then the latest the predecessor task can finish is the successor task's calculated finish date less any applicable offset. • **FinishToStart**—If **Project.Type.Schedule Rule** is 'FromStart', then the earliest the successor task can start is the predecessor task's calculated finish date plus any applicable offset. Else, if **Project.Type.ScheduleRule** is 'FromFinish', then the latest the predecessor task can finish is prior to the successor task's calculated start date less any applicable offset. • **None**—the task dependency is ignored when calculating task start and finish dates. • **StartToFinish**—If **Project.Type.Schedule Rule** is 'FromStart', then the earliest the successor task can finish is the predecessor task's calculated start date plus any applicable offset. Else, if **Project.Type.Schedule Rule** is 'FromFinish', then the latest the predecessor task can finish is the successor task's calculated finish date less any applicable offset. • **StartToStart**—If **Project.Type.Schedule Rule** is 'FromStart', then the earliest the successor task can start is the predecessor task's calculated start date plus any applicable offset. Else, if **Project.Type.ScheduleRule** is 'FromFinish', then the latest the predecessor task can start is the successor task's calculated start date less any applicable offset. **Default value:** None For more information about how this field is used, see "Predecessor relationships" on page 2170.	String (Enum)	
Task	A reference to the successor task. This is the task that comes second (after the predecessor) in the task relationship defined by this record. **Referenced table:** Task	Reference	Yes

Predecessor table – calculated and set fields

The following describes the calculated and set fields in the Predecessor table. For an introduction to this table, and descriptions of its input fields, see "Predecessor table" on page 488.

Table 6.220: Calculated Predecessor (ProjMgmt) fields

Field name	Description	Data type	Key
IsRecursive	Indicates if a recursive relationship exists between the predecessor and successor task. Valid values are • **N**—relationship is not recursive. • **Y**—relationship is recursive; the Predecessor task associated with this record is a dependent on completion of the Successor task through some other predecessor/successor relationship(s) defined in this table.	Boolean	

ProcessInstance table

The ProcessInstance table identifies all of the process instances in RapidResponse. A process instance is created from a process defined in RapidResponse, and is comprised of activities that are assigned to performers.

Each record in the ProcessInstance table contains fields that hold process-level details such as name, the start date, and status.

Table 6.221: ProcessInstance (ProcOrch) fields

Field name	Description	Data type	Key
CreatedDate Time	Specifies when the process instance was created.	DateTime	
Historical	Specifies whether the process instance is historical.	Boolean	
Name	The name of this process instance.	String	Yes
OwnerId	RapidResponse user ID of the process instance owner.	String	
StartDate	The date the process instance is supposed to start. This date is determined when the process instance is created.	Date	

Table 6.221: ProcessInstance (ProcOrch) fields

Field name	Description	Data type	Key
Status	Current status of the process instance. Valid values are: • NotStarted • InProgress • Finished	Enum	
TemplateName	The name of the process from which this process instance was created.	String	
Type	The type of this process instance. The type determines the calendar used by the process instance. **Referenced table:** ProcessInstanceType	Reference	

ProcessInstance – table calculated and set fields

The following describes the calculated and set fields in the ProcessInstance table. For an introduction to this table, and descriptions of its input fields, see "ProcessInstance table" on page 491

Table 6.222: ProcessInstance (ProcOrch) fields

Field name	Description	Data type	Key
ActualFinish Date	Based on the actual finish dates of activities in this process instance. If the process instance has activities, then the date of the last activity to be finished is used. If the process instance does not have any activities, then the ExpectedFinishDate is used.	Date	
ActualStartDate	Based on the actual start dates of activities that belong to this process instance. If the process instance has activities, then the date of the first activity to be started is used. If the process instance does not have any activities, then the ExpectedStartDate is used.	Date	
ExpectedFinish Date	Based on the expected start dates of activities that belong to this process instance. If the process instance has activities, the date of the latest activity expected to finish is used. If the process instance does not have any activities, then the ExpectedStartDate is used.	Date	

Table 6.222: ProcessInstance (ProcOrch) fields

Field name	Description	Data type	Key
ExpectedStart Date	The date of the first day of the process instance. If the first day of the process instance does not fall on a date in Type.Calendar, then the next date in Type.Calendar is used.	Date	
Activities	The set of activities that belong to this process instance.	Set	
Notifications	A set of notifications for this process instance.	Set	

ProductFamily table

The **ProductFamily** table can be used to group together parts that have similarities in design, production, or usage. This allows for planning or reporting related parts at an aggregate level.

Table 6.223: ProductFamily (Mfg) fields

Field name	Description	Data type	Key
Description	Descriptive information about this product family.	String	
Value	A unique string identifier for this product family.	String	Yes

ProductFamily table – calculated and set fields

The following describes the calculated and set fields in the **ProductFamily** table. For an introduction to this table, and descriptions of its input fields, see "ProductFamily table" on page 493.

Table 6.224: ProductFamily (Mfg) fields

Field name	Description	Data type	Key
Parts	Set of Part records associated with this ProductFamily.	Set	

ProductionGroup table

The **ProductionGroup** table describes the properties for groups of parts produced using production wheels. Each production group is allocated amounts of constraint for major and minor changeovers and a maximum amount of constraint that can be consumed by the group. In addition, each group is assigned a priority to manage when the group is produced with other groups that have equal part sequences.

This table was added in Service Update 1902.

Table 6.225: ProductionGroup(Mfg) fields

Field name	Description	Data type	Key
Description	A description of the production group.	String	
MajorCleanup	The amount of constraint required to move from producing parts in this production group to producing parts in another group. It models the time required to clean the shared resource/line/machinery after producing the parts in this group. Measured in constraint units.	Quantity	
MajorSetup	The amount of constraint required to move to producing parts in this production group after having produced parts in another group. It models the time required to prepare the shared resource/line/machinery to produce parts in this group. Measured in constraint units.	Quantity	
MaximumConstraintConsumption	The maximum amount of constraint that can be consumed by this production group in a production wheel cycle. This value is expressed as a fraction. For example, if this value is set to 0.5 and there is 500 constraint available in a cycle, this production group can use no more than 250 constraint in that cycle. The maximum constraint consumption includes the constraint used to produce each part in the group, the constraint required to set up and clean up for the group, and the constraint used to changeover between each part in the group. Except for MajorCleanUp, when this limit is reached you cannot plan for parts associated with this production group in this cycle. The amount of constraint allocated to MajorCleanUp for a production group can cause this maximum to exceed it limit and allow planning to continue. Default value: 0 The counter for MaximumConstraintConsumption is reset at the start of each cycle.	Quantity	
MinorChangeOver	The amount of constraint required to change between production each part in this production group.	Quantity	
Name	A unique identifier for this production group record.	String	Yes

Table 6.225: ProductionGroup(Mfg) fields

Field name	Description	Data type	Key
Priority	The priority associated with this production group if PartSequences are equal. Supply for production is sorted using the following criteria: 1. Production wheel priority 2. Production wheel name 3. Supply demand date 4. Part sequence 5. Production group priority	Integer	
Site	The site associated with this production group. **Referenced table:** Site	Reference	Yes

ProductionGroup table – calculated and set fields

The following describes the calculated and set fields in the **ProductionGroup** table. For an introduction to this table, and descriptions of its input fields, see "ProductionGroup table" on page 493

Table 6.226: ProductionGroup(Mfg) fields

Field name	Description	Data type	Key
PartSources	Set of PartSource records associated with this production group.	Set	

ProductionRecurrence table

The **ProductionRecurrence** table defines how often a part can be made in a production wheel. The recurrence can be assigned to a part or to the segment a part is associated with. The calendar used to set the recurrence is the same calendar assigned to the selected production wheel.

You can offset production cycles to stagger when parts are built by adding an offset to the recurrence. For example, if the changeover cost between two parts (Part A and Part B) in a production group is high, you might want to produce them on the same production wheel but not in the same cycles of that wheel. The table below illustrates an example of how you can use an offset to set a production pattern for each part that produces them in separate cycles.

Part	Recurrence	Offset	Production Pattern
A	2	0	Cycles 1, 3, 5, and so forth
B	2	1	Cycles 2, 4, 6, and so forth

This table was added in Service Update 1902.

Table 6.227: ProductionRecurrence (Mfg) fields

Field name	Description	Data type	Key
Description	A description of the production recurrence.	String	
Offset	The number of cycles production of a part is offset by. An offset of 0 starts production of a part in cycle 1. An offset of 1 starts production of a part in cycle 2 and an offset of 2 starts production of a part in cycle 3 and so forth. For example, if Part A has a recurrence of 3 and an offset of 1, Part A can still be produced in every third cycle of a production wheel but it starts 1 cycle later. If the production wheel has 9 cycles, Part A can be built in cycles 2, 5, and 8.	Integer	
Recurrence	Identifies which cycles in the production wheel can produce the selected part. For example, if Part A is assigned a recurrence of 3 it can be produced in every third cycle of a production wheel. Part A can be built in cycle 1, 4, 7, 10, and so forth. If a part is assigned a recurrence of 1 that part can be produced in every cycle of the production wheel. Default value =1 **Note**: Negative values and zero are treated as the default value of 1.	Integer	
Value	A unique identifier for this production recurrence record.	String	Yes

ProductionRecurrence table – calculated and set fields

The following describes the calculated and set fields in the **ProductionRecurrence** table. For an introduction to this table, and descriptions of its input fields, see "ProductionRecurrence table" on page 495

Table 6.228: ProductionRecurrence(Mfg) fields

Field name	Description	Data type	Key
PartSources	Set of PartSource records associated with this production recurrence.	Set	
Segments	Set of Segment records associated with this production recurrence.	Set	

ProductionWheel table

The **ProductionWheel** table defines properties for production wheels such as wheel durations, cycle lengths, and order priority.

This table was added in Service Update 1902.

Table 6.229: ProductionWheel(Mfg) fields

Field name	Description	Data type	Key
Calendar	A reference to the calendar used by the selected production wheel. **Referenced table:** Calendar		
CalendarInterval	The number of calendar intervals in a production cycle. When combined with the interval it gives the size of the cycle. For example, a production wheel with a Calender of week and a CalendarInterval of 2 makes the cycle size 2 weeks. Default value: 1	Integer	
Description	A description of this production wheel.	String	
EffectiveInDate	The date when you want the production wheel cycle to start. This date cannot be Past, Future, or Undefined. Along with the EffectiveOutDate this field defines the period over which this production wheel record is effective.	Date	
EffectiveOutDate	The date when you want the production wheel to stop. If this date falls in the middle of a cycle, the cycle will complete first. This date cannot be Past or Undefined. Along with EffectiveInDate this field defines the period over which this production wheel record is effective.	Date	
FirstEffectiveDate	The specific date when this production wheel can start. This calculated date is calibrated using the calendar for the selected production cycle. For example, if the first effective date is January 11, 2019 and the cycle uses a week calendar (Monday to Sunday), then the first date that the wheel can start is Monday, January 7, 2019.	Date (calculated)	
LastEffectiveDate	The specific date when this production wheel can stop. This calculated date is calibrated using the calendar for the selected production cycle. For example, if the last effective date is January 23, 2019 and the cycle count is set to 2, then the last date the wheel can stop is February 3, 2019.	Date (calculated)	
Name	A unique identifier for this production wheel record.	String	Yes

Table 6.229: ProductionWheel(Mfg) fields

Field name	Description	Data type	Key
Priority	The order this production wheel is processed in when there are multiple production wheels in the same time frame. This priority is also used to select which production wheel to use when a part has multiple effective part sources in different production wheels. When priorities are equal for the production wheels running in the same time frame, then the production wheel name is used to determine the order.	Integer	
Type	A reference to the control table that contains the rules and values used to manage production wheels in RapidResponse. **Referenced table:** ProductionWheelType	Reference	
Site	The site associated with this production wheel. **Referenced table:** Site	Reference	Yes

ProductionWheel table – calculated and set fields

The following describes the calculated and set fields in the **ProductionWheel** table. For an introduction to this table, and descriptions of its input fields, see "ProductionWheel table" on page 496

Table 6.230: ProductionWheel(Mfg) fields

Field name	Description	Data type	Key
PartSequences	Set of PartSequence records associated with this production wheel.	Set	
PartSources	Set of PartSource records associated with thisproduction wheel.	Set	
ProductionWheelConstraints	Set of ProductionWheelConstraint records associated with this production wheel.	Set	

ProductionWheelConstraint table

The **ProductionWheelConstraint** table describes the constraint parameters that affect production wheels.

This table was added in Service Update 1902.

Table 6.231: ProductionWheelConstraint(Mfg) fields

Field name	Description	Data type	Key
Constraint	A reference to constraint associated with this ProductionWheelConstraint record. **Referenced table**: Constraint	Reference	
MinimumConstraintConsumption	The minimum fraction of constraint that can be consumed in a cycle. This value is a target you set. Default value: 0 **Note:** Constraint used in building parts and in major and minor changeovers is counted in the total amount of constraint consumed in the cycle.	Quantity	
ProductionWheel	A reference to the production wheel associated with this ProductionWheelConstraint record. **Referenced table**: ProductionWheel	Reference	Yes

ProfilePoint table

This table contains data points for profiles (curves) stored in PointProfile table and used in generating statistical forecast for new-product-introduction (NPI) and end-of-life (EOL) items. Each point contains an index (for sorting), quantity, and as a reference to the PointProfile record it applies to.

This table supports Sales and Operations Planning in RapidResponse. Values in this table are maintained through the **S&OP Forecast Item** workbook in RapidResponse. For more information about profiles for NPI and EOL items, see the the *RapidResponse Applications Guide*.

Table 6.232: ProfilePoint (Mfg) fields

Field name	Description	Data type	Key
Id	A unique identifier for this point. When profile points are added in RapidResponse, the Index value is converted to a string and stored in this field.	String	Yes
Index	Index of this point on the profile. Used for sorting.	Integer	
Profile	A reference to the profile this point pertains to. **Referenced table:** PointsProfile	Reference	Yes
Quantity	The quantity of this point in the profile.	Quantity	

Project table

The **Project** table identifies all named projects in RapidResponse. A project is typically comprised of many related tasks or work items that together achieve a definable end goal (such as, delivering a particular good or service). The tasks that make up a given project are those that reference it from the **Task** table. Each record in the **Project** table contains input fields holding project-level details such as name, default start or finish date, project manager, status, and so on. In addition, this table reports calculated project-level details such as the start or finish dates determined by RapidResponse, and any resource, material, or penalty costs applied to the project.

This table's records can be edited using the **Project Manager** workbook included with RapidResponse.

Table 6.233: Project (ProjMgmt) fields

Field name	Description	Data type	Key
Baseline	Indicates if this project is a baseline. After a project has been set as a baseline in RapidResponse, certain calculated fields in this table as well as the **Task** table always return the values they held at the point when the project was baselined. Valid values are: • **N**—project is not a baseline. • **Y**—project is a baseline. **Note:** For more information about setting projects as baselines, see the *RapidResponse User Guide*.	Boolean	
BonusDate	The date on or before which bonuses can potentially be applied to this project. Bonuses are calculated based on the referenced **BonusSchedule** and **ProjectType** values, and can be applied to projects that finish on or before this date (bonuses can accumulate between **CalcFinishDate** and **BonusDate**).	Date	
BonusSchedule	The name of the bonuses schedule used for calculating project bonuses. Together with the rules defined on the project type, this determines how bonuses are calculated at the project level. **Referenced table:** BonusSchedule (Nullable)	Reference	
Customer	The customer, if any, associated with the project. **Referenced table:** Customer (this reference is nullable)	Reference	
Description	A description of this project.	String	

Table 6.233: Project (ProjMgmt) fields

Field name	Description	Data type	Key
FinishDate	An input finish date for the project. If this project has a **ProjectType.ScheduleRule** of "FromFinish", this is the latest possible finish date for any task in the project (used as the default finish date for the last task in the project). RapidResponse also calculates a realistic project finish date as reported in the **CalcFinishDate** field.	Date	
Group	The project group, if any, this project belongs to. **Referenced table:** ProjectGroup (this reference is nullable)	Reference	
HoursPerDay	Standard hours per day that can be worked on task's in this project.	Quantity	
Manager	The project manager assigned responsibility for this project. **Referenced table:** ProjectManager (this reference is nullable)	Reference	
Name	A unique name for this project. This is value is referenced from the **Task.Project** field.	String	Yes
PenaltyDate	The date from which penalties can potentially accumulate to this project. Penalty costs are calculated based on the referenced **PenaltySchedule** and **ProjectType** values, and can be applied between this date and **CalcFinishDate**. For more information about how this field is used, see "Penalties" on page 2191.	Date	
PenaltySchedule	The name of the penalty schedule used for calculating project penalties. Together with the rules defined on the project type, this determines how penalties are calculated at the project level. **Referenced table:** PenaltySchedule (this reference is nullable)	Reference	

Table 6.233: Project (ProjMgmt) fields

Field name	Description	Data type	Key
RateAdjustment	An optional percentage adjustment to be applied to the standard and overtime rates charged for any resources assigned to tasks in this project. For example, all resources assigned to a specific customer project might be discounted. If the adjustment represents a premium charged on resources rates, a positive value should be specified. If the adjustment represents a discount applied to resource rates, a negative value should be specified. For example, .05 indicates a 5 percent premium while -.1 indicates a 10 percent discount. Note that if there is an adjustment specified at a more granular level in the project, then that value is used instead of this one. For example, adjustments can also be specified for individual resources and/or tasks in the project. For more information, see "Resource rate adjustments" on page 2189.	Quantity	
RunDate	The project's current working or "as of" date. This date is meant to separate past activities from future activities in the project schedule. Typically, it might be set to today's date or a date in the very recent past. When **ProjectType.PlanningRule** is set to "DateDriven", this value is also used in scheduling tasks and defines the earliest date on which any new work can commence.	Date	
RunDateTimeOfDay	Specifies if the value provided in the **RunDate** field should be interpreted as the start or the end of the given date, and hence specific point from which new task work can be scheduled. Valid values are: • **StartOfDay**—RunDate applies to the start of the given day. • **EndOfDay**—RunDate applies to the end of the given day. • **Default value**: StartOfDay	String (Enum)	
Site	The site associated with this project. **Referenced table:** Core::Site	Reference	Yes
StartDate	An input start date for the project. If this project has a **ProjectType.ScheduleRule** of "FromStart", this is the earliest possible start date for task in the project (used as the default start date for the first task in the project). RapidResponse also calculates a realistic project start date as reported in the **CalcStartDate** field.	Date	

Table 6.233: Project (ProjMgmt) fields

Field name	Description	Data type	Key
Status	The status of the project. Typically, used to indicate the project's level of completion. **Referenced table:** ProjectStatus	Reference	
Type	A value associated with processing rules that control certain calculations at the project level, such as how project dates and penalties are determined. **Referenced table:** ProjectType	Reference	

Project table – calculated and set fields

The following describes the calculated and set fields in the Project table. For an introduction to this table, and descriptions of its input fields, see "Project table" on page 500.

Table 6.234: Calculated Project (ProjMgmt) fields

Field name	Description	Data type	Key
ActualMaterial Cost	The rolled up actual material costs from all tasks in the project that are assigned to specific demand and/or supply orders.	Money	
ActualTaskCost	The rolled up actual costs associated with completing this task that aren't reflected in the actual resource or material costs. Based on values defined in the **Task.ActualCost** field for tasks in this project.	Money	
Bonus	Bonuses earned at the project level. Project bonuses can only be earned on dates between **CalcFinishDate** and **BonusDate**, where the **BonusSchedule** field references a valid bonus schedule, and the referenced **ProjectType.BonusRule** value is other than "None". For more information about how this field is calculated, see "Bonuses" on page 2196. **Note:** Any task-level bonuses are added to this value and together reported in the **Project.CumulativeBonus** field.	Money	
CalcFinishDate	The calculated finish date for the project. Set to the latest finish date of any task within the project.	Date	
CalcStartDate	The calculated start date for the project. Set to the earliest start date of any task within the project.	Date	

Table 6.234: Calculated Project (ProjMgmt) fields

Field name	Description	Data type	Key
CalcState	The calculated state of progress for this project (based on the **CalcState** values found across all of its tasks). Valid values are: • **Completed**—all tasks in the project are finished. • **InProgress**—at least one task in the project has started but not yet finished. • **NotStarted**—no tasks in the project have started.	String (Enum)	
Cumulative Bonus	Total value of all bonus earned by this project. This field sums all bonuses applied to tasks throughout the projects and adds that to the value in the **Bonus** field.	Money	
Cumulative Penalty Cost	Total penalty costs applicable to this project. This field sums all penalty costs incurred by tasks throughout the projects and adds that to the value in the **PenaltyCost** field.	Money	
MaterialCost	The rolled up planned material costs from all tasks in the project that have material part links defined.	Money	
MaterialRevenue	The rolled up material revenue from all tasks in the projects that demand links defined.	Money	
PenaltyCost	Penalty costs incurred at the project level. Penalty costs can only be incurred on project dates between **PenaltyDate** and **CalcFinishDate**, where the **PenaltySchedule** field references a valid penalty schedule, and the referenced **ProjectType.PenaltyRule** value is other than "None". For more information about how this field is calculated, see "Penalties" on page 2191. **Note:** Any task-level penalties are added to this value and together reported in the **Project.CumulativePenaltyCost** field.	Money	
ResourceActual FixedCost	Actual fixed labor costs incurred during project execution from all resource assignments made to tasks in this project.	Money	
ResourceActual OvertimeCost	Actual overtime labor costs incurred during project execution from all resources working on tasks in excess of their maximum hours per day.	Money	
ResourceActual StandardCost	Actual standard labor costs incurred during project execution from all resources working on tasks up to their maximum hours per day.	Money	

Table 6.234: Calculated Project (ProjMgmt) fields

Field name	Description	Data type	Key
ResourceFixed Cost	The rolled up value of all one-time fixed costs incurred from each assignment of a resource to a task in this project.	Money	
Resource Overtime Cost	The rolled up value of all overtime costs incurred by resources assigned to tasks in this project.	Money	
ResourceStandard Cost	The rolled up value of all standard hour working costs incurred by resources assigned to tasks in this project.	Money	
TaskCost	The rolled up planned costs at the task level, that aren't reflected in resource or material costs, from all tasks in this project. Miscellaneous planned cost at the task level is defined in the **Task.Cost** field.	Money	
TaskRevenue	The rolled up revenue associated with all tasks in this project.	Money	
CriticalPath	Set of CriticalPath records that identify all task's and related items on the project's critical path.	Set	
Tasks	Set of Task records that contain all tasks belonging to the project.	Set	

ProjectedLeadTime table

The **ProjectedLeadTime** table contains lead times projected by the Machine Learning server for a set of **ItemSource** records. The projected lead times are processed based on the **AutomatedLeadTimeType** settings for the **ItemSource**. For more information, see "AutomatedLeadTimeType table" on page 678.

The accepted lead time changes are copied to the **TimePhasedPartSourceLeadTime** table, either because they should be accepted automatically or because the user has accepted them manually. For more information, see the TimePhasedPartSourceLeadTime table.

This table was added in Version 2016.2, Service Update 21.

Table 6.235: ProjectedLeadTime (Mfg) fields

Field name	Description	Data type	Key
EffectiveInDate	The effective date (inclusive) since when the lead time value is taken into consideration.	Date	Yes
FixedLeadTime	The projected fixed lead time.	Quantity	

Table 6.235: ProjectedLeadTime (Mfg) fields

Field name	Description	Data type	Key
ItemSource	The **ItemSource** (Part + Source) associated with the lead times. **Referenced table:** ItemSource **Reference syntax:** ItemSource.Part, ItemSource.Source	Reference	Yes
LowerBound	The lower bound of the confidence interval.	Quantity	
RevisedLeadTime	The revised lead time used to override the projected lead time. **Note:** This value should be non-negative.	Quantity	
UpperBound	The upper bound of the confidence interval.	Quantity	

ProjectedYield table

The **ProjectedYield** table contains yield values projected by the Machine Learning server for a set of **ItemSource** records. The projected yields are processed based on the **AutomatedYieldType** settings for the **ItemSource**. For more information, see "AutomatedYieldType table" on page 683.

The accepted yield changes are copied to the **TimePhasedYield** table, either because they should be accepted automatically or because the user has accepted them manually. For more information, see the TimePhasedYield table.

Table 6.236: ProjectedYield (Mfg) fields

Field name	Description	Data type	Key
EffectiveInDate	The effective date (inclusive) since when the yield value is taken into consideration.	Date	Yes
Yield	The projected yield as a fraction in the range 0..1.	Quantity	
ItemSource	The **ItemSource** (Part + Source) associated with the yields. **Referenced table:** ItemSource **Reference syntax:** ItemSource.Part, ItemSource.Source	Reference	Yes
LowerBound	The lower bound of the confidence interval.	Quantity	
RevisedYield	The revised yield used to override the projected yield. **Note:** This value should be non-negative.	Quantity	
UpperBound	The upper bound of the confidence interval.	Quantity	

ProjectedYield table – calculated and set fields

The following describes the calculated and set fields in the **ProjectedYield** table.

Table 6.237: Calculated HistoricalReceipt (Mfg) fields

Field name	Description	Data type	Key
CalcEffectiveYield	Calculated field. Reports the projected Yield value in "user-facing" units (as defined by **ItemSource.CalcYieldUsageRule**)	Quantity	
CalcEffectiveUpperBound	Reports the upper bounds of the confidence intervals, converted into "user-facing" units (as defined by **ItemSource.CalcYieldUsageRule**)	Quantity	
CalcEffectiveLowerBound	Reports the lower bounds of the confidence intervals, converted into "user-facing" units (as defined by **ItemSource.CalcYieldUsageRule**)	Quantity	

ProjectGroup table

The **ProjectGroup** table defines group names that can be assigned to projects. These are meant to categorize and group similar types of projects together, and can be used to aid in project-level tracking and filtering.

This table's records can be edited using the **Project Groups** worksheet in the **Project Master Data** workbook included with RapidResponse.

Table 6.238: ProjectGroup (ProjMgmt) fields

Field name	Description	Data type	Key
Description	A description of this project group.	String	
Name	A string value used to identify this project group. This value is referenced from the Group field on the Project table.	String	Yes

ProjectGroup table – calculated and set fields

The following describes the calculated and set fields in the ProjectGroup table. For an introduction to this table, and descriptions of its input fields, see "ProjectGroup table" on page 507.

Table 6.239: Calculated ProjectGroup (ProjMgmt) fields

Field name	Description	Data type	Key
Projects	Set of Project records that reference this ProjectGroup value.	Set	

ProjectManager table

The **ProjectManager** table identifies all projects managers that can be assigned responsibility for projects.

This table's records can be edited using the **Project Managers** worksheet in the **Project Master Data** workbook included with RapidResponse.

Table 6.240: ProjectManager (ProjMgmt) fields

Field name	Description	Data type	Key
Name	The name of the project manager. This value is referenced from the Manager field on the **Project** table.	String	Yes

ProjectManager table – calculated and set fields

The following describes the calculated and set fields in the ProjectManager table. For an introduction to this table, and descriptions of its input fields, see "ProjectManager table" on page 508.

Table 6.241: Calculated ProjectManager (ProjMgmt) fields

Field name	Description	Data type	Key
Projects	Set of Project records that reference this ProjectManager value.	Set	

ProjectStatus table

The **ProjectStatus** table defines status values that can be assigned to projects. These values are meant indicate a project's level of completion and can be used in filtering down to specific projects of interest. For example, projects might be identified as Planned, Open, Delayed, or Completed.

This table's records can be edited using the **Project Status** worksheet in the **Project Master Data** workbook included with RapidResponse.

Table 6.242: ProjectStatus (ProjMgmt) fields

Field name	Description	Data type	Key
Description	A description of this project status type.	String	
Value	A string value used to identify this project status type. This value is referenced from the Status field on the Project table.	String	Yes

ProjectStatus table – calculated and set fields

The following describes the calculated and set fields in the ProjectStatus table. For an introduction to this table, and descriptions of its input fields, see "ProjectStatus table" on page 508.

Table 6.243: Calculated ProjectStatus (ProjMgmt) fields

Field name	Description	Data type	Key
Projects	Set of Project records that reference this ProjectStatus value.	Set	

RangeOfCoveragePartOverride table

This table is applicable only to range of coverage parts; that is, parts where the **SafetyStockQuantityRule** field on either the **SafetyStockPolicy** or **PartType** table (as appropriate) is set to either "RangeOfCoverage", "RangeOfCoverageLeadTime" or "RangeOfCoverageTimePhased". It allows for certain parameters to be specified on a part by part basis overriding the settings in the **RangeOfCoverage** table.

By default, parts take their range of coverage parameters from the RangeOfCoverage table (through the **SafetyStockPolicy.RangeOfCoverage** reference). However, for any part referenced from a record in this table, the **RangeOfCoveragePartOverride** parameters are used in place of the corresponding fields in the **RangeOfCoverage** table.

Note: For more information on the RangeOfCoverage table, see "RangeOfCoverage table" on page 855.

Table 6.244: RangeOfCoveragePartOverride (Mfg) fields

Field name	Description	Data type	Key
Average Requirement IntervalCount	The number of **RangeOfCoverage.Average RequirementIntervals** to consider demand from when calculating average daily demands. **Default value:** 0	Integer	
Average Requirement Interval LeadTimeCount	An optional parameter that is applicable only when **SafetyStockQuantityRule** is set to "RangeOfCoverageLeadTime". It represents a factor of lead time that can be used to extend the period over which demands are accumulated when calculating the average daily demand. The value provided in this field is then multiplied by the longest lead time for the part expressed as a number of **RangeOfCoverage.AverageRequirement Intervals** (rounded up, if necessary). The result of that calculation is then added to the value in **AverageRequirementIntervalCount** to determine the total number of calendar units over which demands should be accumulated. **Default value:** 0	Integer	
Average Requirement IntervalOffset	A parameter allowing the average daily demand calculations to be offset a specified number of **RangeOfCoverage.AverageRequirement Intervals** from the start of the **RangeOfCoverageInterval**. For example, if **RangeOfCoverage.AverageRequirement Interval** is set to "Weekly" and this value is set to "3", then the average daily demand requirements will be calculated starting 3 weeks after the start of the **RangeOfCoverageInterval**. **Default value:** 0	Integer	
Part	A reference to the part this set of range of coverage parameters should apply to. If a reference exists to a given part, then all range of coverage parameters in this table override the corresponding fields in the **RangeOfCoverage** table. However, all parts not referenced from this table continue to take all their range of coverage parameters from the **RangeOfCoverage** table. **Referenced table:** Part **Reference Syntax**: Part.Name, Part.Site	Reference	Yes

Table 6.244: RangeOfCoveragePartOverride (Mfg) fields

Field name	Description	Data type	Key
ThresholdFactor Lower	A factor used along with the **Part.RangeOfCoverageBuffer field** to set the lower threshold limit for a given range of coverage interval as follows: • **LowerLimit** = Calculated SafetyStockLevel + (Part.RangeOfCoverageBuffer * ThresholdFactorLower) When the safety stock level is calculated for a range of coverage interval, this limit and an upper limit (using the **ThresholdFactorUpper** value) are also calculated. If the existing safety stock level (from the previous range of coverage interval) falls within these limits, then the new calculated level is discarded and the existing safety stock level remains effective. This is intended to avoid making minor changes to the safety stock level which might have only insignificant benefit. If, however, the existing safety stock level falls outside these limits, then the new calculated safety stock level becomes effective. **Default value:** 0	Quantity	
ThresholdFactor Upper	A factor used along with the **Part.RangeOfCoverageBuffer** field to set the upper threshold limit for a given range of coverage interval as follows: • **UpperLimit** = Calculated SafetyStockLevel + (Part.RangeOfCoverageBuffer * ThresholdFactorUpper) When the safety stock level is calculated for a given range of coverage interval, this limit and a lower limit (using the **ThresholdFactorLower** value) are also calculated. If the existing safety stock level (from the previous range of coverage interval) falls within these limits, then the new calculated level is discarded and the existing safety stock level remains effective. This is intended to avoid making minor changes to the safety stock level which might have only insignificant benefit. If, however, the existing safety stock level falls outside these limits, then the new calculated safety stock level becomes effective. **Default value:** 0	Quantity	

ReferenceForecastDimension table

This table was originally used to identify the dimensions of reference forecasts supporting Sales and Operations Planning in RapidResponse. Note that reference forecasts are no longer used in Sales and Operations Planning, however this table supports assumption functionality (is referenced by the **Assumption** table).

Table 6.245: ReferenceForecastDimension (Mfg) fields

Field name	Description	Data type	Key
Description	A description of the reference forecast dimension	String	
Id	An identifier for the reference forecast dimension. Data in this field should identify the hierarchy and level the dimension is created for.	String	Yes

ReferenceForecastTarget table

This table originally used to identify the hierarchy element that a dimension of a reference forecast is applied to and supported Sales and Operations Planning in RapidResponse. Note that reference forecasts are no longer used in Sales and Operations Planning, however, this table supports assumption functionality (is referenced by the **Assumption** table).

Table 6.246: ReferenceForecastTarget (Mfg) fields

Field name	Description	Data type	Key
Dimension	The dimension the reference forecast target is created under. **Referenced table:** ReferenceForecastDimension **Reference Syntax:** Dimension.Id	Reference	
Id	The hierarchy element the reference forecast is created for. Values in this field can refer to the full path of the hierarchy element (each element at each level between the top level and the target, separated by | characters), or to the value of the target element, depending on how the hierarchy is specified. Typically, the full path should be used if a hierarchy element has more than one parent in the hierarchy. For example, in a hierarchy that has levels for division and product family, if the same product family is carried by two different divisions, the full path should be used in this field.	String	Yes

ReferenceForecastTarget table – calculated and set fields

The following describes the calculated and set fields in the **ReferenceForecastTarget** table. For an introduction to this table, and descriptions of its input fields, see "ReferenceForecastTarget table" on page 512.

Table 6.247: Calculated ReferenceForecastTarget (Mfg) fields

Field name	Description	Data type	Key
Assumptions	Set of assumptions associated with this record.	Set	

ReferencePart table

The **ReferencePart** table lists alternate names for parts. The alternate name could be an old name for the part, the name of a product line, or the name used by a different site or a contract manufacturer. The relationship between this table and the **Part** table varies depending on how it is used. For example, if this table is used to group parts together, many parts will have the same reference part. However, if this table is used to hold old names for parts, each part will have a unique reference part.

This table is primarily used to show relationships between part names for data publishers and subscribers. It holds the name of the part as used by the subscriber and is referenced by the **Part.ReferencePart** field (**Part.Name** holds the name of the part as used by the publisher). This allows a subscriber to see part data in a context that makes sense to them.

This table can also be used in any of the following ways:

- to hold a generic part name to be used by different company divisions that identify the same part using different naming conventions.
- to allow multi-site part analysis by grouping the parts from different locations into a common reference part.
- to group multiple parts into a common product line.
- to maintain and display old part names if a new part naming convention has been adopted.
- left empty if not being used.

Table 6.248: ReferencePart (Mfg) fields

Field name	Description	Data type	Key
Value	The name of the reference part.	Reference	

ReferencePart table – calculated and set fields

The following describes the calculated and set fields in the **ReferencePart** table.

Table 6.249: Calculated ReferencePart (Mfg) fields

Field name	Description	Data type	Key
Parts	The set of parts that refer to this reference part.	Set	

Region table

The **Region** table can be used to identify geographic entities for grouping sites, customers, and suppliers. For example, it might hold values identifying states, countries, or sales territories. A secondary level of regional identifiers is available through the **RegionGroup** reference.

Table 6.250: Region(Mfg) fields

Field name	Description	Data type	Key
Id	A unique id for this region. For example, NE-US.	String	Yes
Name	The full descriptive name for this region. For example, Northeast United States.	String	
RegionGroup	A reference to an additional regional group this region belongs to. For example, if the **Id** field is used to identify countries, this field might indicate the international region each country belongs to. **Referenced table:** RegionGroup (Nullable)	Reference	

Region table – calculated and set fields

The following describes the calculated and set fields in the **Region** table. For an introduction to this table, and descriptions of its input fields, see "Region table" on page 514.

Table 6.251: Calculated Region(Mfg) fields

Field name	Description	Data type	Key
Customers	The set of customers associated with this region.	Set	
Sites	The set of sites associated with this region.	Set	
Suppliers	The set of suppliers associated with this region.	Set	

RegionGroup table

The **RegionGroup** table identifies geographic entities for grouping regions. For example, if the **Region** table identifies individual states or sales territories, then this table might be used to identify the country or international region to which those regions belong.

Table 6.252: RegionGroup (Mfg) fields

Field name	Description	Data type	Key
Id	A unique identifier for this regional group. For example, NA.	String	Yes
Name	The full descriptive name for this regional group. For example, North America.	String	

RegionGroup table – calculated and set fields

For an introduction to this table, and descriptions of its input fields, see "RegionGroup table" on page 514.

Table 6.253: Calculated RegionGroup (Mfg) fields

Field name	Description	Data type	Key
Region	The set of regions	Set	

RegressionModel table

The **RegressionModel** table stores the names of regression models that are defined for use with multiple linear regression in statistical forecasting. The records in this table are referenced by records in the RegressionModelTerm table and the values in both tables represent a regression formula.

The **RegressionModel** table supports the Demand Planning and Statistical Forecasting application in RapidResponse. This table was introduced in version 2016.2 Service Update 27.

Table 6.254: RegressionModel (Mfg) fields

Field name	Description	Data type	Key
Name	The unique name for this regression model.	String	Yes
Description	A description of this regression model.	String	

Regression Model table – calculated and set fields

The following describes the calculated and set fields in the **RegressionModel** table.

Table 6.255: Set fields RegressionModel (Mfg) fields

Field name	Description	Data type	Key
ForecastItemParameters	Set of forecast items for this regression model.	Set	
RegressionModelTerms	Set of historical demands for the forecast item.	Set	

RegressionModelTerm table

The records stored in this table contain information about the model terms that are associated with regressors, also known as predictors or independent variables, that are used with multiple linear regression in statistical forecasting. The records in this table reference the RegressionModel table and the values in both tables represent a regression formula.

The **RegressionModelTerm** table supports the Demand Planning and Statistical Forecasting application in RapidResponse. This table was introduced in version 2016.2 Service Update 27.

Table 6.256: RegressionModelTerm (Mfg) fields

Field name	Description	Data type	Key
Lag	The number of past **ForecastItemParametersType.IntervalsCalendar** periods that are specified for calculating the lagged regressor values in the statistical forecast. Negative values will be ignored because they violate causality. **Default value**: 0	Quantity	
Model	A reference to the regression model that this model term is used in. **Referenced table**: RegressionModel	Reference	Yes
Name	The unique name used to identify this model term.	String	Yes
ProcessingRule	This value indicates if a regressor is being used in the statistical forecast calculation for a forecast item. Valid values are: **Ignore**–The regressor is not being used to calculate the statistical forecast for a forecast item. **Use**–The regressor is being used to calculate the statistical forecast for a forecast item. **Default value**: Use	String (Enum)	
Regressor	A reference to the regressor that is associated with this model term. **Referenced table**: Regressor	Reference	

Regressor table

The **Regressor** table stores records for regressors that are used with multiple linear regression in statistical forecasting. Multiple linear regression is a statistical forecasting method that uses multiple regressors to predict the future demand of a forecast item. A regressor, which is also known as an independent variable, causal factor, or predictor, is a factor that may drive the demand for a forecast item. You can use the regressors to help determine the future demand for the forecast item in the statistical forecast. For example, you could use product discounts, holidays, or weather values as regressors.

This table is referenced by the RegressionModelTerm and RegressorValue tables.

The **Regressor** table supports the Demand Planning and Statistical Forecasting application in RapidResponse. This table was introduced in version 2016.2 Service Update 27.

Table 6.257: Regressor (Mfg) fields

Field name	Description	Data type	Key
AttachToForecastItemParameters	This field is in the Solutions namespace.	Boolean	
Name	The unique name for this regressor.	String	Yes
Description	A description that was provided about this regressor.	String	
Category	A reference to the category to which this regressor belongs. Categories are used to organize regressors in the S&OP Regressor Management workbook. **Referenced table:** RegressorCategory (Nullable)	Reference	

Regressor table – calculated and set fields

The following describes the calculated and set fields in the **Regressor** table.

Table 6.258: Set fields Regressor (Mfg) fields

Field name	Description	Data type	Key
RegressionModelTerms	Set regression model terms for this regressor.	Set	
RegressorValues	Set of regressor values for this regressor.	Set	

RegressorCategory table

This table is used to group regressors into categories. Regressors are used with multiple linear regression in statistical forecasting. You can use categories to organize regressors in the S&OP Regressor Management workbook.

The RegressorCategory table supports the Demand Planning and Statistical Forecasting application in RapidResponse. This table was introduced in version 2016.2 Service Update 27.

Table 6.259: RegressorCategory (Mfg) fields

Field name	Description	Data type	Key
Name	The unique name that identifies a group of regressors.	String	Yes
Description	A description that was provided for the regressor category.	String	

RegressorCategory table – calculated and set fields

The following describes the calculated and set fields in the **RegressorCategory** table.

Table 6.260: Set fields RegressorCategory (Mfg) fields

Field name	Description	Data type	Key
Regressors	Set of regressors that belong to this category.	Set	

RegressorValue table

The **RegressorValue** table stores individual values for a regressor on a given date. Regressors are used with multiple linear regression in statistical forecasting. A regressor, which is also known as an independent variable, causal factor, or predictor, is a factor that may drive the demand for a forecast item. The value of a regressor depends on the type of regressor that you are using in the statistical forecast. For example, you could use values that represent past product discounts, holidays, or temperatures, as long as they are know to drive the demand for a product.

The values in the **RegressorValue** table are used to calculate **ForecastItemParametersRegressor.Quantity**, which is bucketed using **ForecastItemParametersActual.Date**. The **RegressorValue.Date** does not need to match **ForecastItemParametersActual.Date**. You can also have multiple **RegressorValue** records in the interval between two **ForecastItemParametersActual** dates. However, if within this interval there are dates with no **RegressorValue** records, a **RegressorValue.Quantity** remains in effect starting at **RegressorValue.Date** until one day prior to **RegressorValue.Date** of the next available **RegressorValue** record. For more information, about how **ForecastItemParametersRegressor.Quantity** is calculated, see "ForecastItemParametersRegressor table " on page 1067 and "Multiple linear regression calculations" on page 2047.

If there is no **RegressorValue** record associated with a date that is equal to, or earlier than the first **ForecastItemParametersActual.Date** in the historical data series, then a **RegressorValue.Quantity** of zero is applied.

It is also important to note that the values stored in this table are not only historical values. The values within the following range are taken into account in the calculation:

RunDate - **ForecastItemParameters.HistoricalIntervalCount** to **RunDate** + **ForecastItemParameters.ForecastIntervalCount**.

The **RegressorValue** table supports the Demand Planning and Statistical Forecasting application in RapidResponse. This table was introduced in version 2016.2 Service Update 27.

Table 6.261: RegressorValue (Mfg) fields

Field name	Description	Data type	Key
Regressor	A reference to the regressor that is associated with this value. **Referenced table:** Regressor (Nullable)	Reference	Yes
Date	The date to start using this regressor value record.	Date	Yes
Quantity	The quantity of this regressor on a given date.	Quantity	

Resource table

The **Resource** table identifies all resources that can be assigned to complete work on project tasks. Each resource's available working time, as well as the fixed and hourly costs associated with its task assignments, are also specified here. However, if time-phased resource costs are required, then the values in this table can be overridden by date by adding records to the **ResourceCosts** table. Similarly, if time-phased resource availabilities are required, then the values in this table can be overridden by date by adding records to the **ResourceAvailable** table.

This table's records can be edited using the **Resources** worksheet in the **Project Resource Master Data** workbook included with RapidResponse.

Table 6.262: Resource (ProjMgmt) fields

Field name	Description	Data type	Key
DataDate	The first date on which this resource's load details can be generated in the **ResourceDataByDate** table. The referenced **ResourceType**.**Calendar** and **ResourceType.ReportLimit** values then together specify how long after this date that resource load details will be generated in the **ResourceDataByDate** table.	Date	
FixedCost	A set cost incurred each time the resource is assigned to a task, and independent of the amount of time actually spent on the task. Based on the **TaskType.FixedCostAccrualRule** setting for a given task, this cost can be incurred either when the task starts, the task finishes, or spread evenly across all days the resource is assigned to the task.	Money	
Group	A reference to the group this resource belongs to. **Referenced table:** ResourceGroup (Nullable)	Reference	
HoursPerDay	Standard number of hours available per working day for one unit of this resource. The number of hours specified here equates to a single unit as specified in the **MaximumUnits** field. For example, if **MaximumUnits** is 1 and this value is 8, then the resource can do a maximum of 8 hours work per day before it is seen as over allocated and overtime costs incurred.	Quantity	
Initials	Initials belonging to this resource. Might be used to simplify or shorten the reporting of multiple resource names assigned to a task.	String	
MaximumUnits	Maximum number of units available per working day for this resource, where each unit corresponds to the value in the **HoursPerDay** field. For example, if **HoursPerDay** is 8 and this value is 1, then the resource can do a maximum of 8 hours work per day before it is seen as over allocated and overtime costs incurred.	Quantity	
Name	A string value used to identify this resource (for example, it is referenced when assigning resources to tasks).	String	Yes
OvertimeRate	Hourly overtime rate for this resource. Any load generated against this resource on a given day, beyond the maximum units specified, is billed at this rate. For example, if **HoursPerDay** is 6 and **MaximumUnits** is 1.5, this rate is applied to all hours worked in excess of nine per day by this resource.	Money	

Table 6.262: Resource (ProjMgmt) fields

Field name	Description	Data type	Key
Site	The site associated with this resource. **Referenced table:** Site	Reference	Yes
StandardRate	Standard hourly rate for this resource. Any load generated against this resource on a given day, up until the maximum units specified, is billed at this rate. For example, if **HoursPerDay** is 8 and **MaximumUnits** is 1.25, this rate is applied to each of the first ten hours worked per day by this resource.	Money	
Type	A value associated with processing rules that control certain calculations at the resource level, such as how costs associated with resource loads are apportioned. **Referenced table:** ResourceType	Reference	

Resource table – calculated and set fields

The following describes the calculated and set fields in the Resource table. For an introduction to this table, and descriptions of its input fields, see "Resource table" on page 519.

Table 6.263: Calculated Resource (ProjMgmt) fields

Field name	Description	Data type	Key
Overloaded	Indicates if the resource is overloaded at any point. A resource is considered overloaded if there is at least one date on which the total load placed on the resource (from assignments across all projects) exceeds the maximum units available for the resource. Valid values are: • Y • N	Boolean	
OverloadedDate	If a resource is overloaded, this field reports the earliest date on which the total load placed against the resource exceeds its maximum units available.	Date	
Assignments	Set of ResourceAssignment records that reference this Resource value.	Set	
Availables	Set of ResourceAvailable records that reference this Resource value.	Set	

Table 6.263: Calculated Resource (ProjMgmt) fields

Field name	Description	Data type	Key
Calendar Exceptions	Set of ResourceCalendarException records that reference this Resource value.	Set	
Costs	Set of ResourceCosts records that reference this Resource value.	Set	
DataByDate	Set of ResourceDataByDate records that reference this Resource value.	Set	
Loads	Set of ResourceLoad records that reference this Resource value.	Set	

ResourceAssignment table

The **ResourceAssignment** table defines the assignments of resources to specific project tasks. Assignments are made in units, based on the effective **HoursPerDay** and **MaximumUnits** values from either the **Resource** or **ResourceAvailable** tables, and are applicable for the duration of the resource's task assignment. If required, the resource units assigned can be time-phased during the duration of a task by adding values to the **ResourceAssignmentAvailable** table.

If using Task-based worksheets automatically configured for project management, such as in the **Project Plan** workbook included with RapidResponse, values can be added to this table through the **Resources** tab of the **Task Information** dialog box.

Table 6.264: ResourceAssignment (ProjMgmt) fields

Field name	Description	Data type	Key
ActualWork	If **Task.DurationType** is "FixedWorkAndRate", then this value is used together with the **RemainingWork** field to determine the work for the task (and hence impacts the calculated task duration). Otherwise, this field is not used in calculating task duration.	Quantity	
ApplyRate Adjustment	Indicates if the resource rate adjustment specified in the **RateAdjustment** field will be applied to for this resource assignment. Valid values are: • **N**—adjustment can be applied. • **Y**—adjustment is ignored.	Boolean	
BaseKey	A unique string identifier for this resource assignment.	String	Yes

Table 6.264: ResourceAssignment (ProjMgmt) fields

Field name	Description	Data type	Key
Rate	If **Task**.**DurationType** is "FixedWorkAndRate", then this value is used to determine the rate at which the resource completes work on the task (and hence impacts the calculated task duration). Otherwise, this field is ignored. For example, assume a single resource assigned to a task with ActualWork of "5"and RemainingWork of "1", along with a Rate of "2". The calculated task duration would then be 3; that is, (5 + 1)/ 2.	Quantity	
RateAdjustment	An optional percentage adjustment to be applied to the standard and overtime rates charged for the resource when working on this s task. This value is considered only if **ApplyRateAdjustment** is set to "Y". If the adjustment represents a premium charged on resources rates, a positive value should be specified. If the adjustment represents a discount applied to resource rates, a negative value should be specified. For example, .05 indicates a 5 percent premium while -.1 indicates a 10 percent discount. Note that this adjustment overrides any other resource rate adjustments specified at the project or task levels. For more information, see "Resource rate adjustments" on page 2189.	Quantity	
RemainingWork	If **Task**.**DurationType** is "FixedWorkAndRate", then this value is used together with the **ActualWork** field to determine the work for the task (and hence impacts the calculated task duration). Otherwise, this field is not used in calculating task duration.	Quantity	
Resource	A reference to the resource that has been assigned to a task. **Referenced table:** Resource	Reference	Yes
Task	A reference to the task that has had a resource assigned to it. **Referenced table:** Task	Reference	Yes
Units	The amount of the resource, expressed in terms of maximum units per day, that should be assigned to the task. For example, if a resource's **HoursPerDay** is set to 8, and its **MaximumUnits** is set to 1, then a value of .75 in this field assigns it for 6 hours a day to the task. Depending on the **Task.DurationType** setting, this value also impacts calculated task durations as discussed in "Task durations" on page 2176.	Quantity	

ResourceAssignment table – calculated and set fields

The following describes the calculated and set fields in the ResourceAssignment table. For an introduction to this table, and descriptions of its input fields, see "ResourceAssignment table" on page 522.

Table 6.265: Calculated ResourceAssignment (ProjMgmt) fields

Field name	Description	Data type	Key
EffectiveRate Adjustment	Indicates the rate adjustment, if any, to be applied to the resource's standard and overtime rates when assigned to this task. For example, .05 indicates a 5 percent premium is applied to the resource rate, and -.12 indicates a 12 percent discount is applied to the resource rate.	Quantity	
EffectiveRate Adjustment Source	Indicates the source of the rate adjustment effective for this resource task assignment. Resource rate adjustments can be specified in up to six different tables, but only one adjustment is ever effective for a given resource assignment. The list below shows the order of priority for different rate adjustment sources (items higher in the list always take precedence over lower items). Valid values are: • **ResourceAssignment**—adjustment is defined for a given resource and task assignment. • **ResourceGroupTaskOverride**—adjustment is defined for all members of a resource group assigned to a given task. • **Task**—adjustment is defined for all resources assigned to a given task. • **ResourceProjectOverride**—adjustment is defined for a particular resource assigned to any tasks in a given project. • **ResourceGroupProjectOverride**—adjustment is defined for all members of a resource group assigned to any tasks in a given project. • **Project**—adjustment is defined for all resources assigned to any tasks in a given project. • **None**—no rate adjustment is applicable for the resource assignment.	String (Enum)	
Starting Unadjusted OvertimeRate	The hourly overtime rate that applies to the resource on the task's start date. This value comes from either of the **Resource** or **ResourceCost** tables and does not take into account any rate adjustments.	Money	

Table 6.265: Calculated ResourceAssignment (ProjMgmt) fields

Field name	Description	Data type	Key
Starting Unadjusted StandardRate	The hourly standard rate that applies to the resource on the task's start date. This value comes from either of the **Resource** or **ResourceCost** tables and does not take into account any rate adjustments.	Money	
StartingFixed Cost	The fixed cost that applies to the resource on the task's start date.	Money	
Availables	Set of ResourceAssignmentAvailable records that reference this ResourceAssignment value.	Set	

ResourceAssignmentAvailable table

The **ResourceAssignmentAvailable** table is used to override the units of work specified on the assignment of a resource to a task. For example, this might be done when a resource is not fully available for some portion of the task due to other scheduled task commitments. Each record in this table references a record in the **ResourceAssignment** table and allows for the original Units value specified on the resource assignment to be overridden as of a particular date.

Values in this table are only used if the task whose resource assignment is being overridden has resource leveling enabled (that is, it has a **TaskType.LevelResources** setting of "Y"). Otherwise, if **TaskType.LevelResources** = "N". then any applicable records in this table are ignored and the assignment values specified in the **ResourceAssignment** table are always used by the task.

This table's records can be edited using the **Resource Assignment Available Override** worksheet in the **Project Resource Master Data** included with RapidResponse.

Table 6.266: ResourceAssignmentAvailable (ProjMgmt) fields

Field name	Description	Data type	Key
EffectiveDate	Date on which the units specified for this referenced resource assignment take effect. The specified units are then assumed to be effective until the next EffectiveDate specified on a record in this table for the resource assignment. For all dates before the earliest EffectiveDate for a given resource, and in cases of resources that do not have values specified in this table, the units specified on the **ResourceAssignment** table are used by default.	Date	
Id	A unique string identifier for this resource assignment override.	String	Yes
Resource Assignment	A reference to the record defining the task and resource whose assigned units are to be overridden as of the specified effective date. **Referenced table:** ResourceAssignment	Reference	Yes

Table 6.266: ResourceAssignmentAvailable (ProjMgmt) fields

Field name	Description	Data type	Key
Units	Amount of the resource in units that should be assigned to the task as of the effective date specified. For example, if a resource's **HoursPerDay** is set to 8, and its **MaximumUnits** is set to 1, then a value of .5 in this field assigns it to the task for 4 hours a day.	Quantity	

ResourceAvailable table

The **ResourceAvailable** table is used to specify time-phased availability for resources that can be used to complete project tasks. For example, a resource might be on vacation for a period, or have a temporary increase in their working capacity.

When a resource has availabilities defined in this table that are effective on a given date, those values are used instead of the corresponding **HoursPerDay** and **MaximumUnits** fields in the **Resource** table. The resource availabilities defined in this table also respect the **TaskType.LevelResources** setting which can be used to ensure that resources assigned to tasks are not assigned beyond the maximum units specified. For example, this setting can be used to ensure no load is placed against a resource while on vacation.

This table's records can be edited using the **Resource Available Overrides** worksheet in the **Project Resource Master Data** included with RapidResponse.

Table 6.267: ResourceAvailable (ProjMgmt) fields

Field name	Description	Data type	Key
EffectiveDate	Date on which the resource availability specified for this resource takes effect. The specified **HoursPerDay** and **MaximumUnits** are then assumed to be effective until the next EffectiveDate specified on a record in this table for the resource. For example, suppose a resource goes on vacation and has 0 units available beginning on the date their vacation begins. At the end of that vacation period, another record should be added to this table specifying the number of units available once the resource returns to work. For all dates before the earliest **EffectiveDate** for a given resource, and in cases of resources that do not have any values specified in this table, the **HoursPerDay** and **MaximumUnits** from the **Resource** table are used by default.	Date	
HoursPerDay	The new standard number of hours available per working day for one unit of this resource. The number of hours specified here equates to a single unit as specified in the **MaximumUnits** field. For example, if **MaximumUnits** is 1 and this value is 8, then the resource can do a maximum of 8 hours work per day before it is seen as over allocated and overtime costs incurred.	Quantity	

Table 6.267: ResourceAvailable (ProjMgmt) fields

Field name	Description	Data type	Key
Id	A unique string identifier for this resource availability override.	String	Yes
MaximumUnits	The new maximum number of units available per working day for this resource, where each unit corresponds to the value in the **HoursPerDay** field. For example, if **HoursPerDay** is 4 and this value is 2, then the resource can do a maximum of 8 hours work per day before it is seen as over allocated and overtime costs incurred. Note also that **TaskType.LevelResources** value for a given task also influences the usage of this field (except in cases of "fixed duration" tasks). If **LevelResources** is set to "N", then resource allocations to a task in excess of the maximum units specified here are seen as over allocations and overtime costs are incurred accordingly. However, if **LevelResources** is set to "Y", then resource allocations to a task are not allowed to exceed the maximum units specified here, and the calculated task duration and finish dates are moved out as required.	Quantity	
Resource	A reference to the resource whose standard availability is being overridden by the values in this record. **Referenced table:** Resource	Reference	Yes

ResourceCalendarException table

The **ResourceCalendarException** table is used to specify exceptions to the hours per day available from resources on given days of the week. For example, a resource might not work on Mondays or might only work half-days on Fridays.

Each record in this table identifies a resource and the hours per day it can work on a specific day of the week. The values provided here override the effective **HoursPerDay** value for the resource in either the **Resource** or **ResourceAvailable** tables (for the specified day of the week only).

This table's records can be edited using the **Resource Calendar Overrides** worksheet in the **Project Master Data** workbook included with RapidResponse.

Table 6.268: ResourceCalendarException (ProjMgmt) fields

Field name	Description	Data type	Key
DayOfWeek	The day of the week for which the standard hours per day specified on either the **Resource** or **ResourceAvailable** table should be overridden. Valid values are: • Monday • Tuesday • Wednesday • Thursday • Friday • Saturday • Sunday **Note:** In order to apply a new **HoursPerDay** value to a given day of the week for the resource, the day specified must exist on the **ResourceType.Calendar** value used by the resource. For example, if the resource's calendar is a standard 5 day workday, then records entered here for Saturday or Sunday would be ignored.	String (Enum)	
EffectiveDate	Date on which the hours per day specified for this resource and day of the week takes effect. The specified hours are then effective until the next **EffectiveDate** in this table for the specified **Resource** and **DayOfWeek** combination.	Date	
HoursPerDay	The new standard hours per day available for this resource on the specified day of the week. The number of hours specified here equates to a single unit as specified in the **MaximumUnits** field on either the **Resource** or **ResourceAvailable** tables. For example, if **DayOfWeek** is 'Friday', **MaximumUnits** is '1', and this value is '4', then four hours per day can be worked on a Friday before the resource is seen as over allocated and any overtime costs incurred.	Quantity	
Id	A unique string identifier for this resource calendar exception.	String	Yes
Resource	A reference to the resource this calendar exception applies to. **Referenced table:** Resource	Reference	Yes

ResourceCostActual table

The **ResourceCostActual** table can be used to input the actual standard and/or overtime hours worked by a resource on a given date, and reports the calculated costs associated with those hours. This data is typically inputted once a project has moved past the planning stage into execution and allows for a comparison of actual and estimated costs. For example, RapidResponse includes standard reports that

show planned and actual project costs in a burndown chart; these reports rely on the actual resource details being provided in this table.

This table's records can be edited using the Project Resource Management workbook included with RapidResponse.

Table 6.269: ResourceCostActual (ProjMgmt) fields

Field name	Description	Data type	Key
Date	The date on which the actual costs accrued to the resource from this task assignment.	Date	
FixedCost	Any fixed (set) cost incurred on this date from assigning the resource to the task.	Money	
Id	A unique string identifier for this record.	String	Yes
OvertimeHours	The number of hours worked by the resource on the task that exceed the resources's maximum hours per day.	Quantity	
Resource Assignment	A reference to the specific resource and task assignment to which the actual hours specified on this record apply. **Referenced table:** ResourceAssignment	Reference	Yes
StandardHours	The number of hours worked by the resource on the task that do not exceed resources's maximum hours per day.	Quantity	

ResourceCostActual table – calculated and set fields

The following describes the calculated and set fields in the **ResourceCostActual** table. For an introduction to this table, and descriptions of its input fields, see "ResourceCostActual table" on page 528.

Table 6.270: ResourceCostActual (ProjMgmt) calculated and fields

Field name	Description	Data type	Key
OvertimeCost	The calculated overtime cost incurred on this date from the resource's work on the task assignment. This value is calculated by multiplying the value given in the **OvertimeHours** field by the resource's hourly overtime rate. The resource's hourly overtime rate comes from the **OvertimeRate** field on either the **Resource** table or the **ResourceCosts** table (if it has an effective record for the resource on this date), and is subject to any applicable project or task-level rate adjustments.	Money	
StandardCost	Reports the standard cost incurred on a this date from the resource's work on the task assignment. This value is calculated by multiplying the value given in the **OvertimeHours** field by the resource's hourly overtime rate. The resource's hourly overtime rate comes from the **StandardRate** field on either the **Resource** table or the **ResourceCosts** table (if it has an effective record for the resource on this date), and is subject to any applicable project or task-level rate adjustments.	Money	

ResourceCosts table

The **ResourceCosts** tables is used to specify time-phased costs, such as standard and overtime rates, associated with using a particular resource to complete tasks. When a resource has cost values in this table that are effective on a given date, those values are used instead of the corresponding values provided in the **Resource** table.

This table's records can be edited using the **Resource Cost Overrides** worksheet in the **Project Resource Master Data** workbook included with RapidResponse.

Table 6.271: ResourceCosts (ProjMgmt) fields

Field name	Description	Data type	Key
EffectiveDate	Date on which the cost values specified for this resource take effect. The specified costs are then assumed to be effective until the next EffectiveDate specified on a record in this table for the resource. For all dates before the earliest EffectiveDate for a given resource, and in cases of resources that do not have values specified in this table, the cost values from the **Resource** table are used by default.	Date	
FixedCost	A new set cost incurred each time the resource is assigned to a task, and independent of the amount of time actually spent on the task. Based on the **TaskType.FixedCostAccrualRule** setting for a given task, this cost can be incurred either when the task starts, the task finishes, or spread evenly across all days the resource is assigned to the task.	Money	
Id	A unique string identifier for this set of resource costs.	String	Yes
OvertimeRate	Overtime rate for this resource. Any load generated against this resource on a given day, beyond the maximum units specified, is billed at this hourly rate. For example, if **Resource.MaximumUnits** is '1' and **Resource.HoursPerDay** is '8', this rate is applied to all hours worked in excess of eight per day by this resource.	Money	
Resource	A reference to the resource these time-phased costs apply to. **Referenced table:** Resource	Reference	Yes
StandardRate	Standard hourly rate for this resource. Any load generated against this resource on a given day, up until the maximum units specified, is billed at this rate. For example, if **Resource.HoursPerDay** is 10 and **Resource.MaximumUnits** is 1., this rate is applied to each of the first ten hours worked per day by this resource.	Money	

ResourceGroup table

The **ResourceGroup** table defines group names that can be assigned to resources. These are meant to categorize and group similar types of resources together. For example, resource groups might be created to identify job titles associated with the resources on a project. These can be used to aid in resource-level tracking and filtering.

This table's records can be edited using the **Resource Groups** worksheet in the **Project Resource Master Data** workbook included with RapidResponse.

Table 6.272: ResourceGroup (ProjMgmt) fields

Field name	Description	Data type	Key
Description	A description of this resource group.	String	
Name	A string value used to identify this resource group. This value is referenced from the Group field on the **Resource** table.	String	Yes

ResourceGroup table – calculated and set fields

The following describes the calculated and set fields in the ResourceGroup table. For an introduction to this table, and descriptions of its input fields, see "ResourceGroup table" on page 531.

Table 6.273: Calculated ResourceGroup (ProjMgmt) fields

Field name	Description	Data type	Key
Resources	Set of Resource records that reference this ResourceGroup value.	Set	

ResourceGroupProjectOverride table

The **ResourceGroupProjectOverride** table is used to apply project-specific adjustments to the standard and overtime rates charged by members of a particular resource group. For example, all engineers assigned to a specific customer project might have their rates discounted.

Adjustments specified in this table override any specified for the project itself. However, if there are adjustments specified at a more granular level, then those values are used instead of the ones in this table. For example, examples can be specified for individual resources and/or tasks in the project. For more information, see "Resource rate adjustments" on page 2189.

Table 6.274: ResourceGroupProjectOverride (ProjMgmt) fields

Field name	Description	Data type	Key
Project	The project in which the rate adjustment will be applied to members of the referenced resource group. **Referenced table:** Project	Reference	Yes
RateAdjustment	The percentage adjustment to be applied to the standard and overtime rates charged by members of the resource group when assigned to tasks in this project. If the adjustment represents a premium charged on resources rates, a positive value should be specified. If the adjustment represents a discount applied to resource rates, a negative value should be specified. For example, .05 indicates a 5 percent premium while -.1 indicates a 10 percent discount.	Quantity	
ResourceGroup	The group whose resources will have a rate adjustment applied when assigned to tasks in the referenced project. **Referenced table:** ResourceGroup	Reference	Yes

ResourceGroupTaskOverride table

The **ResourceGroupTaskOverride** table is used to apply task-specific adjustments to the standard and overtime rates charged by members of a particular resource group. For example, a premium might be applied to any engineers assigned to a particular task.

Adjustments specified in this table override any specified at the project level or on the task itself. However, if a task-based adjustment is specified for an individual member of the resource group, than that value is used instead of the one in this table. For more information, see "Resource rate adjustments" on page 2189.

Table 6.275: ResourceGroupTaskOverride (ProjMgmt) fields

Field name	Description	Data type	Key
RateAdjustment	The percentage adjustment to be applied to the standard and overtime rates charged by members of the resource group when assigned to the referenced task. If the adjustment represents a premium charged on resources rates, a positive value should be specified. If the adjustment represents a discount applied to resource rates, a negative value should be specified. For example, .2 indicates a 20 percent premium while -.12 indicates a 12 percent discount.	Quantity	
ResourceGroup	The resource group whose members will have a rate adjustment applied when assigned to the referenced task. **Referenced table:** ResourceGroup	Reference	Yes

Table 6.275: ResourceGroupTaskOverride (ProjMgmt) fields

Field name	Description	Data type	Key
Task	The task to which a rate adjustment will be applied when any members of the referenced resource group are assigned to it. **Referenced table:** Task	Reference	Yes

ResourceProjectOverride table

The **ResourceGroupProjectOverride** table is used to apply project-specific adjustments to the standard and overtime rates charged by a particular resource. For example, all a specific person working on a customer project might bill at a premium rate.

Adjustments specified in this table override any specified for the project or project and resource group. However, if there are adjustments specified at the task level, then those values are used instead of the ones in this table. For more information, see "Resource rate adjustments" on page 2189.

Table 6.276: ResourceProjectOverride (ProjMgmt) fields

Field name	Description	Data type	Key
Project	The project in which the adjustment will be applied to the rate charged by the referenced resource. **Referenced table:** Project table	Reference	Yes
RateAdjustment	The percentage adjustment to be applied to the standard and overtime rates charged by this resource when assigned to tasks in the project. If the adjustment represents a premium charged on resources rates, a positive value should be specified. If the adjustment represents a discount applied to resource rates, a negative value should be specified. For example, .05 indicates a 5 percent premium while -.1 indicates a 10 percent discount.	Quantity	
Resource	The specific resource that will have a rate adjustment applied when assigned to tasks in the referenced project. **Referenced table:** Resource table	Reference	Yes

Routing table

The **Routing** table contains routing codes that are used to group together the sequence of operations used in the making of a part. It is referenced by the **OperationSequence** table that identifies operation sequences and groups together work center operations from the **CRPOperation**. It is also directly referenced by the **Operation** table to provide compatibility with earlier versions of RapidResponse when operations were stored in that table and directly referenced routings (the **CRPOperation** table is recommended for all new purposes).

This table then serves as the link between work orders and the specific work center operations required in their production. The **Routing** table is referenced by **PartSource** table which uses it to determine all operations required to produce a new planned order from the part source, and also by the **ScheduledReceipt** table which uses it to determine all operations required to produce the order.

The **Routing** table supports the optional capacity calculations.

Table 6.277: Routing (Mfg) fields

Field name	Description	Data type	Key
Id	The unique identifier for the routing. **Default value**: blank string	String	Yes
Site	The site associated with this routing. **Note:** This field is optional. A system or data administrator can choose whether it uniquely identifies records in the table, or is ignored in queries, and not shown in insert definitions, dialog boxes, or the Data Sources and Mapping window. **Referenced table:** Site	Reference	Yes

Routing table – calculated and set fields

The following describes the calculated and set fields in the Routing table. For an introduction to this table, and descriptions of its input fields, see "Routing table" on page 534.

Table 6.278: Calculated Routing (Mfg) fields

Field name	Description	Data type	Key
AlternateRoutings	A set of **AlternateRouting** records. These records are used for information purposes only.	Set	
LoadsNewOrder Planned	Set of calculated LoadOperationNewOrderPlanned records reporting load from a planned order through an operation that belongs to this routing.	Set	
LoadsReceipts Current	Set of calculated LoadOperationReceiptsCurrent records reporting load from a scheduled receipt (based on current due dates) through an operation that belongs to this routing.	Set	
LoadsReceipts Planned	Set of calculated LoadOperationReceiptsPlanned records reporting load from a scheduled receipt (based on recommended due dates) through an operation that belongs to this routing.	Set	
Operations	A set of **Operation** records that belong to this routing.	Set	

Table 6.278: Calculated Routing (Mfg) fields

Field name	Description	Data type	Key
PartSources	Set of **PartSource** records using this Routing to determine the operations required when a new planned order is built.	Set	
ScheduledReceipts	Set of **ScheduledReceipt** records that use this routing to determine the operations required in their production.	Set	
Sequences	A set of **OperationSequence** records that reference this routing and identify a named sequence of operations (from the **CRPOperation** table) belonging to the routing.	Set	

RParameter table

The **RParameter** table identifies optional parameters and associated values to be passed to specific functions in the R statistical programming language. Each parameter and value pair defined in this table must then be associated with a set of R parameters that can be used by forecast items.

This table supports the optional Rforecast capability (and is only applicable when forecasting an item that uses the "Rforecast" forecast model).

Table 6.279: RParameter (Mfg) fields

Field name	Description	Data type	Key
Description	A description of the parameter and associated value defined on this record.	String	
Id	A unique string identifier for this record.	String	Yes
Name	A reference to the named parameter. **Referenced table**: RParameterName **Note:** The following values are ignored if defined as R parameters: damped, fan, find.frequency, h, level, lower, object, phi, upper, y. Most of these are passed to R based on data and field values in RapidResponse.	Reference	
Set	A reference to a named set this parameter belongs to. **Referenced table**: RParameterSet **Note:** Values in the **RParameterSet** table can then be referenced by ForecastItemParameters records for items that want to pass a set of parameters to R during statistical forecast generation.	Reference	Yes
Value	A string containing the value to be associated with the named parameter.	String	

RParameterSet table

The **RParameterSet** table holds named groupings of optional parameters and their values for use in statistic functions in the R programming language. This table is referenced by both the **RParameter** and **ForecastItemParameters** tables.

The **RParameter** table is used to specify values for optional parameters and the specific functions in R that those parameters should be passed to. All entries in the **RParameter** table that reference the same **RParameterSet** record are then treated as a group that can be passed collectively to R forecasting functions.

If the **ForecastItemParameters** table used the "Rforecast" model, and also has its **RParameterSet** reference populated, then parameter values defined in the referenced set will be passed to R for use in generating the statistical forecast. Otherwise, if the item's **RParameterSet** is Null, then no optional parameters are assumed and the forecast is generated using a standard set of parameters in R (many of which have their values set to field values from the **ForecastItemParameters** table). Note that the "Rforecast" model is intended to generate reasonable forecast values without the use of any optional parameters which are generally intended for advanced uses.

The **RParameterSet** table supports the optional R Forecast capability.

Table 6.280: RParameterSet (Mfg) fields

Field name	Description	Data type	Key
Name	A unique name for this group of function parameters.	String	Yes
Description	A description of this parameter set.	String	

RParameterSet table–calculated and set fields

The following describes the calculated and set fields in the **RParameterSet** table. For an introduction to this table, and descriptions of its input fields, see "RParameterSet table " on page 537.

Table 6.281: RParameterSet (Mfg) calculated fields

Field name	Description	Data type	Key
Details	Set of **BestFitProfileDetail** records that use this parameter set. **Referenced table:** BestFitProfileDetail	Set	
ForecastItem Parameters	Set of **ForecastItemParameters** records that use this parameter set. **Referenced table:** ForecastItemParameter	Set	
RParameters	Set of **RParameter** records that identify the parameter values that define this parameter set. **Referenced table:** RParameter	Set	

SafetyLeadTimeProfile table

The **SafetyLeadTimeProfile** table holds named profiles that enable time-phased safety lead time. Safety lead time is meant to account for some level of uncertainty in demand and supply, and is used to adjust demand dates and set planned order due dates.

Each profile should be referenced by records in the **SafetyLeadTimeProfileDetail** table that define the safety lead time values that apply within specified date ranges. If a part references a profile through the **Part.SafetyLeadTimeProfile** field, then its safety lead time values come from the set of **SafetyLeadTimeProfileDetail** records associated with that referenced profile (in addition to any safety lead time defined at the part source level).

Otherwise, if a **Part** record has a Null reference to this table, its safety lead time is taken from the non-time phased value in **Part.SafetyLeadTime** (in addition to any safety lead time defined at the part source level).

Note that in order for a part to use a referenced profile and its detail records, the part must use **PartType.SafetyLeadTime** value of either "Y" or "Soft" (otherwise, safety lead time won't be used when planning supply to demand). Also, if safety lead time should be applied to demand request dates and/or only used in cases where doing so won't make other demands worse off, then use of settings on the **OrderPriority.TwoDatePlanningRule** field should be considered.

This table was added in Version 2016.2

Table 6.282: SafetyLeadTimeProfile (Mfg) fields

Field name	Description	Data type	Key
Description	A description of this safety lead time profile. For example, it might provide descriptive details about the set of **SafetyLeadTimeProfileDetail** records associated with this profile.	String	
Site	The site associated with this profile. **Referenced table:** Site	Reference	Yes
Value	The name of this safety lead time profile. Together with the Site value, this uniquely identifies the profile.	String	Yes

SafetyLeadTimeProfile table – calculated and set fields

The following describes the calculated and set fields in the **SafetyLeadTimeProfile** table. For an introduction to this table, and descriptions of its input fields, see "SafetyLeadTimeProfile table" on page 538.

Table 6.283: Calculated SafetyLeadTimeProfile (Mfg) fields

Field name	Description	Data type	Key
Parts	Set of Part records that use this safety lead time profile.	Set	
SafetyLeadTime ProfileDetails	Set of SafetyLeadTimeProfileDetail records that define the effective dates and associated safety lead time values that comprise this profile.	Set	

SafetyLeadTimeProfileDetail table

The **SafetyLeadTimeProfileDetail** table contains the time-phased safety lead time values that define named profiles in the **SafetyLeadTimeProfile** table.

Each record in this table specifies a safety lead time value to associate with a referenced profile, along with the first date on which that safety lead time value is meant to apply (**EffectiveInDate**) and the last date that value is meant to apply (**EffectiveOutDate**).

When defining records in this table, the effective dates should typically be set so that records belonging to the same profile do not have overlapping date ranges. That is, the **EffectiveInDate** on one record belonging to a given profile should typically not be earlier than the **EffectiveOutDate** on the previous record belonging to that same profile. However, in cases where a given demand date falls within the effective range of multiple **SafetyLeadTimeProDetail** records for profile, the detail record with the latter **EffectiveOutDate** is assumed to be effective.

Note also that if a demand date does not fall within the effective date range of any detail record associated with the part's safety lead time profile, then the value in **Part.SafetyLeadTime** is used instead.

This table was added in Version 2016.2.

Table 6.284: SafetyLeadTimeProfileDetail (Mfg) fields

Field name	Description	Data type	Key
EffectiveInDate	The first date on which the safety lead time defined on this record can be effective (inclusive).	Date	Yes
EffectiveOutDate	The last date on which the safety lead time defined on this record can be effective (inclusive).	Date	

Table 6.284: SafetyLeadTimeProfileDetail (Mfg) fields

Field name	Description	Data type	Key
SafetyLeadTime	Amount of time added to a part's fixed lead time to protect against fluctuations in supply and demand. When planning new supply to satisfy a demand, the demand date is adjusted by this value to determine the planned order due date. Depending on the **PartType.SafetyLeadTimeCalendarRule** setting used the part, this value should be expressed in either the part's **PlanningCalendars.TimeUnits** calendar or the Everyday/Gregorian calendar. **NOTE**: SafetyLeadTime is ignored and not used to offset due dates for safety stock demands.	Quantity	
SafetyLeadTime Profile	A reference to the profile the safety lead time details defined on this record apply to. **Referenced table**: SafetyLeadTimeProfile	Reference	Yes

SafetyStockAverageDemandProfile table

The **SafetyStockAverageDemandProfile** contains optional profiles that can be used to define the horizon over which a safety stock item's historical and/or future demands are collected for use in calculating average demands. These are the average demand calculations that are used as input towards determining the recommended historical and future reorder points.

Each profile in this table is made up an **Offset** value that defines the start or end point for collecting data, a **Multiplier** value that defines a multiple of the item's lead time over which historical data is collected, and an **Extend** value that adds a fixed value to the period over which data is collected. The specific usage of these three fields depends on whether the profile is being used for collecting historical demands or future demands.

When a profile is used to determine a window for collecting historical demands, the values provided in this table are used along with the last date of the historical collection interval defined on the safety stock item and the item's average lead time to define profile start and end dates as follows:

- **Historical start:** `LastDate - Offset - CalcAverageLeadTime * Multiplier - Extend`
- **Historical end:** `LastDate - Offset`

Conversely, when a profile is used to determine a window for collecting future demands, the values provided in this table are used along with the run date and the safety stock item's average lead time to define profile start and end dates as follows:

- **Future start:** `RunDate + Offset`
- **Future end:** `RunDate + Offset + CalcAverageLeadTime * Multiplier + Extend`

The **CalcAverageLeadTime** value used in profile calculations is taken from the calculated field on the **SafetyStockItem** table.

Table 6.285: SafetyStockAverageDemandProfile (Mfg) fields

Field name	Description	Data type	Key
Description	An optional description explaining this average demand profile.	String	
Extend	A fixed number of intervals, expressed in terms of **SafetyStockItem.IntervalsCalendar,** to add to or extend the horizon for calculating average demands (after having accounted for the offset value and applied the lead time multiplier).	Integer	
Multiplier	A multiplier applied to the safety stock item's average lead time, the product of which is then used in determining the size of the window for calculating average demands. **Note:** This field's data type was modified in Version 2016.2, Service Update 4.	Quantity	
Name	A unique name that identifies this average demand profile. Both the **HistoricalAverageDemandProfile** and **FutureAverageDemandProfile** fields on the **SafetyStockItem** table reference this field.	String	Yes
Offset	A fixed number of intervals, expressed in terms of **SafetyStockItem.IntervalsCalendar,** to offset the start/end of the horizon used for collecting demands used in average demand calculations.	Integer	

SafetyStockItem table

The **SafetyStockItem** table is used to configure both single and multi-echelon safety stock items. Each record in this table identifies a specific item (part) for which safety stock recommendations should be made, specifies whether the item is intended for single or multi-echelon safety stock calculations, and contains other parameters applicable to single-echelon, multi-echelon, or both calculations.

Single-echelon safety stock items are used by both the **TimePhasedSafetyStock** and **SafetyStock** functions to generate safety stock and reorder point recommendations for individual parts based on historical data and meant to satisfy a specified service level (optionally, forecast data can also be used to generate future-looking reorder point recommendations). Multi-echelon safety stock items are used by an analytic that generates safety stock recommendations across a network of parts in order to both satisfy service levels defined for customer-facing end items, while also attempting to minimize the total holding cost of that inventory by recommending the strategic placement of that safety stock within the network.

This table was modified in Version 2016.2, Service Update 5. For more information about the calculations it supports, see "Inventory planning and optimization" on page 1935. Note also that the **Inventory Planning** workbook included with RapidResponse can be used to add or modify records in this table, and also reports results of single and multi-echelon safety stock calculations.

Table 6.286: SafetyStockItem (Mfg) fields

Field name	Description	Data type	Key
AverageDemand	A value representing the average historical demand to use for the part in safety stock calculations. Applicable only to non-time phased items and where **Type.StandardDeviationDemandRule** is set to "Manual". Average demand might be manually provided when there is limited historical data available for an item, but its average demand and other parameters are known or estimated from some other means. Note that **AverageDemand** should be expressed in **Type.IntervalsCalendar**.	Quantity	
DemandOutlier MovingAverage Window	The length of the moving average window for historical demand or forecast error. This field is only applicable on items where **OutlierType.DataRule** is set to "MovingAverageError". When using this setting, the threshold value is interpreted depending on the value specified for the **DemandOutlierThreshold** setting. **Default value**: 3 **Note:** This field was added in Version 2016.2, Service Update 5.	Integer	
DemandOutlier Threshold	The (minimum) number of standard deviations away from the mean a demand quantity or forecast error point must be in order to be considered an outlier. Any outliers detected are then removed, smoothed, or ignored, as specified by the setting in the **RemoveDemandOutliers** field. When using this setting, the threshold value is interpreted depending on the specified **OutlierType.DetectionRule**. For example, if the DetectionRule = "Winsorizing", then outliers that are detected are identified as quantities that are outside a specified percentile in the ordered data. For more information, see the **OutlierType.DetectionRule** field. **Default value**: 3 **Note:** This field achieves the same functionality as the **ForecastErrorOutlierThreshold** field and is applicable on items where **Type.StandardDeviationDemandRule** is set to "ForecastError".	Quantity	
DemandOutlier Type	A reference to the **OutlierType** that defines how to process outliers in historical demand or historical forecast error. **Default value**: Null **Referenced table**: OutlierType (Nullable) **Note:** This field was added in Version 2016.2, Service Update 5	Reference	

Table 6.286: SafetyStockItem (Mfg) fields

Field name	Description	Data type	Key
DemandSmoothing AfterIntervalCount	When smoothing demand outliers, this indicates the number of **Type.IntervalsCalendar** periods forward over which to spread the values. This occurs after any backward spreading. This field is only applicable on items where **OutlierType.BelowThresholdRule** is set to "SmoothKeepExcess" or "SmoothRemoveExcess".	Integer	
DemandSmoothing BeforeInterval Count	When smoothing demand outliers, this indicates the number of **Type.IntervalsCalendar** periods backward over which to spread the values. This occurs before any forward spreading. This field is only applicable on items where **OutlierType.AboveThresholdRule** is set to "SmoothKeepExcess" or "SmoothRemoveExcess".	Integer	
Description	An optional description for this safety stock item.	String	
ForecastLag	Number of **Type.AsOfDateCalendar** intervals to look back when collecting historical forecast data for use in forecast error calculations. For example, assume this value is set to "1" and the AsOfDateCalendar is set to "Month". In that case, HistoricalDemandActual records from one month are compared against detail forecast records referencing a HistoricalDemandSeries where the AsOfDate is in the previous month. Similarly, a value of "2" would indicate to compare actuals from one month against the forecast made two months earlier. This field is only applicable on items where **Type.StandardDeviationDemandRule** is set to "ForecastError". **Default value**: 1 (zero and all negative values are interpreted as 1). **Note:** For an example of this field's usage, see "Example 3: Fixed lead time (with forecast error)" on page 1972.	Integer	

Table 6.286: SafetyStockItem (Mfg) fields

Field name	Description	Data type	Key
ForecastError OutlierThreshold	Number of standard deviations away from the mean that a forecast error point must be in order to be considered an outlier. If a point is determined to be an outlier, it is processed based on the setting in **Type.ForecastOutlierProcessingRule** field (for example, outliers might be removed entirely when calculating the standard deviation of forecast error). This field is only applicable on items where **Type.StandardDeviationDemandRule** is set to "ForecastError". **Note:** This field is obsolete (as of Version 2016.2, Service Update 5). To achieve the same functionality, use the **DemandOutlierThreshold** field.	Quantity	
FutureAverage DemandProfile	A reference to a profile, based on lead time multiples and other settings, that defines the horizon to use when determining the average future demand value for use in reorder point calculations. This reference is nullable and can be left blank if all future data points should be used to calculate average future demand. Note that this field supports reorder point calculations applicable to single-echelon safety stock items only. **Referenced table:** SafetyStockAverageDemandProfile (Nullable)	Reference	
FutureInterval Count	The number of **Type.IntervalsCalendar** periods after the run date over which current/forecast demand data should be collected to determine future average demands. This value is also: • Used to calculate details in the **SafetyStockItemFutureDemand** table. The **SafetyStockItemFutureDemand** table is used to calculate days of supply for single-echelon safety stock items. The table is also used to calculate the average future demand that will help determine **SafetyStockTimePhasedResult.FutureReorderPoint** for multi-echelon safety stock items. • Reflected in the quantity that is reported in **SafetyStockResult.AverageFutureDemand**, which helps determine reorder point calculations for single-echelon safety stock items. If this value is less than or equal to zero, then all future demands are used.	Integer	

Table 6.286: SafetyStockItem (Mfg) fields

Field name	Description	Data type	Key
HistoricalAverage DemandProfile	A reference to a profile, based on lead time multiples and other settings, that defines the horizon to use when determining the average historical demand value for use in reorder point calculations. This reference is nullable and can be left blank if all historical data points should be used to calculate average historical demand. **Referenced table:** SafetyStockAverageDemandProfile	Reference	
HistoricalDemand Category	A reference to the historical demand category from which **HistoricalDemandActual** data should be collected for use in safety stock calculations. **Referenced table:** HistoricalDemandCategory	Reference	
HistoricalEndDate	The last date on which to collect historical demand and supply data for use in safety stock calculations (if a date later than RunDate is specified, then `RunDate + 0 Type.IntervalsCalendars` is used instead).	Date	
HistoricalForecast Category	A reference to the historical forecast category. When calculating the standard deviation of forecast error, historical forecast records in the **HistoricalDemandSeriesDetail** are collected for this item only if they match this category through their **Series.Category** reference. This field is only applicable on items where **Type.StandardDeviationDemandRule** is set to "ForecastError" and Type.TimePhasedProcessingRule is either "Ignore" or "DaysOfSupplyBackward" or "DaysOfSupplyForward". **Referenced table:** HistoricalDemandCategory (Nullable)	Reference	

Table 6.286: SafetyStockItem (Mfg) fields

Field name	Description	Data type	Key
HistoricalInterval Count	The number of **Type.IntervalsCalendar** periods before the run date over which to collect historical demand and supply data for use in safety stock calculations. HistoricalIntervalCount should be set to the (positive integer) number of IntervalsCalendar intervals of history to consider. Historical data collection starts the specified number of HistoricalIntervalCount intervals before RunDate, and ends the day before RunDate. If a value less than or equal to 0 is provided in this field, then the **HistoricalEndDate** and **HistoricalStartDate** fields are used to define the period instead. If HistoricalIntervalCount is greater than 0, **HistoricalEndDate** is ignored and a non-null **HistoricalStartDate** will still be considered. The effective start date will be min (HistoricalStartDate, RunDate - HistoricalIntervalCount). **Note:** When specifying a **SafetyStockItem.HistoricalIntervalCount** value for a safety stock item, it needs to adequately reflect both the **SafetyStockItemType.IntervalsCalendar** and **SafetyStockItemType.CycleCalendar** that are selected for that item. This is to ensure that an adequate amount of historical demand and supply data is available for use in safety stock calculations. For example, if **IntervalsCalendar** is set to "monthly" and **CycleCalendar** is "yearly", you would need a minimum **SafetyStockItem.HistoricalIntervalCount** of "12" to provide adequate history.	Integer	

Table 6.286: SafetyStockItem (Mfg) fields

Field name	Description	Data type	Key
HistoricalSkip LeadingZeros	Determines whether **SafetyStockHistoricalDemand** and **SafetyStockHistoricalForecast** records are created for buckets at the beginning of the historical demand period (based on **HistoricalDemandActuals** table) where the demand and forecast quantities are zero (leading zeros), respectively. **Y**—If **HistoricalSkipLeadingZeros** is set to "Y" and **Type.StandardDeviationDemandRule** is set to "ForecastError," the forecast error is computed beginning with the first bucket in the historical demand period for which both the forecast quantity and the demand quantity are not zero. **N**—Leading zeros are not ignored when calculating historical data. **Default value:** N **Note:** Records with zero quantity in the first bucket or buckets of the historical demand period are skipped if **HistoricalSkipLeadingZeros** is set to "Y," but only if all earlier period buckets in the **HistoricalDemandActuals** table have demand quantities of zero. If the first period buckets in the table have demand with positive quantities, leading zeros are not ignored. **Note:** This field was added in Version 2016.2 Service Update 6.	Boolean	
HistoricalStartDate	The first date on which to collect historical demand and supply data for use in safety stock calculations.	Date	
HistoricalSupply Category	A reference to the historical supply category from which **HistoricalSupplyActual** data should be collected for use in determining average lead times (used only when **Type.SupplyVariabilityRule** is set to "Use"). This reference is nullable and can be left empty in cases where lead time variability considerations are not required for safety stock calculations. Note that this field and historical supply calculations apply to single-echelon safety stock calculations only. **Referenced table:** HistoricalSupplyCategory	Reference	
LeadTime	Standard average lead time value to use for the part in single-echelon safety stock calculations. Applicable if **Type.SupplyVariabilityRule** is set to either "Ignore" or "Manual", or if no historical supply data is available (otherwise, lead time is calculated from historical supply data). This value should be expressed primarily in terms of **Type.LeadTimeCalendar** units, only being expressed as **Type.IntervalsCalendar** units when not defined.	Quantity	

Table 6.286: SafetyStockItem (Mfg) fields

Field name	Description	Data type	Key
LeadTimeOutlier MovingAverage Window	The length of the moving average window for historical lead time. This field is only applicable on items where **OutlierType.DataRule** is set to "MovingAverageError". When using this setting, the threshold value is interpreted depending on the value specified for the **LeadTimeOutlierThreshold** setting. **Default value**: 3 **Note:** This field was added in Version 2016.2, Service Update 5 and is used only for SEIP. For MEIO, use **MEIOLeadTime.LeadTimeOutlierMovingAverageWindow**.	Integer	
LeadTime OutlierThreshold	The (minimum) number of standard deviations away from the mean a lead time quantity must be in order to be considered an outlier. Any outliers detected are then removed, smoothed, or ignored, as specified by the setting in the **RemoveDemandOutliers** field. When using this setting, the threshold value is interpreted depending on the specified **OutlierType.DetectionRule**. For example, if the DetectionRule = "Winsorizing", then outliers that are detected are identified as quantities that are outside a specified percentile in the ordered data. For more information, see the **OutlierType.DetectionRule** field. **Default value**: 3 **Note:** This field was added in Version 2016.2, Service Update 5 and is used only for SEIP. For MEIO, use **MEIOLeadTime.LeadTimeOutlierThreshold**.	Quantity	
LeadTime OutlierType	A reference to the **OutlierType** that defines how to process outliers in historical lead time. **Default value**: Null **Referenced table**: OutlierType (Nullable) **Note:** This field was added in Version 2016.2, Service Update 5 and is used only for SEIP. For MEIO, use **MEIOLeadTime.LeadTimeOutlierType**.	Reference	

Table 6.286: SafetyStockItem (Mfg) fields

Field name	Description	Data type	Key
LeadTimeSmoothing AfterIntervalCount	When smoothing historical lead time outliers for safety stock items, this indicates the default number of **Type.IntervalsCalendar** periods forward over which to spread the values. This occurs after any backward spreading. This field is only applicable on items where **OutlierType.BelowThresholdRule** is set to "SmoothKeepExcess" or "SmoothRemoveExcess". **Note:** This field was added in Version 2016.2, Service Update 5 and is used only for SEIP. For MEIO, use **MEIOLeadTime.LeadTimeSmoothingAfterIntervalCount**.	Integer	
LeadTimeSmoothing BeforeIntervalCount	When smoothing historical lead time outliers for safety stock items, this indicates the default number of **Type.IntervalsCalendar** periods backward over which to spread the values. This occurs after any forward spreading. This field is only applicable on items where **OutlierType.AboveThresholdRule** is set to "SmoothKeepExcess" or "SmoothRemoveExcess". **Note:** This field was added in Version 2016.2, Service Update 5 and is used only for SEIP. For MEIO, use **MEIOLeadTime.LeadTimeSmoothingBeforeIntervalCount**.	Integer	
OrderQuantity	If **Type.ServiceLevelRule** is set to "FillRate", this specifies the minimum order quantity value to be used as input when determining the service factor to use in safety stock calculations.	Quantity	
Part	A reference to the part for which safety stock and/or reorder point recommendations should be calculated. **Referenced table:** Part	Reference	Yes

Table 6.286: SafetyStockItem (Mfg) fields

Field name	Description	Data type	Key
ProcessingRule	Indicates the type of safety stock calculations that are applicable to this safety stock item. Valid values are: • **MultiEchelon**—Recommended safety stock levels are calculated for the safety stock item itself as well as other eligible parts in its family (for example, parts in its BillOfMaterial structure). Variability of the safety stock item's historical demands is calculated, and the demand values are subsequently propagated to the lower-level items in its family. Either fixed or variable lead times are used for each item in the family. From this, a level of safety stock and strategic placement of the safety stock across parts in the item's network is recommended. The recommendations are meant to minimize the total cost of holding inventory in the network while satisfying the item's specified service level and service time. If an item is configured for multi-echelon safety stock calculations, ensure that related parts that should be brought into its family have their **MultiEchelonSafetyStockRule** reference set appropriately (this includes the part configured as a SafetyStockItem itself). • **SingleEchelon**—A recommended safety stock level is calculated just for the safety stock item (part) defined on this record. Based on variability of the item's historical demands and (optionally) supply lead times, safety stock is calculated to satisfy the item's specified service level. A recommended reorder point, based on either history or forecast, is also determined. **Default value:** SingleEchelon	String (Enum)	

Table 6.286: SafetyStockItem (Mfg) fields

Field name	Description	Data type	Key
RemoveDemand Outliers	Determines whether outliers in historical data should be removed from the data series (reducing the length of the series, as opposed to adjusting outlier values without changing the length of the series). The **DemandOutlierThreshold** setting defines the number of standard deviations away from the mean an item quantity must be before it is considered an outlier. Valid values are: • **No**—Does not remove outliers. Instead, outliers are adjusted according to the threshold rules on **OutlierType**. • **Yes**—Removes both high and low outliers. • **LowOnly**—Removes only low outliers. • **HighOnly**—Removes only high outliers. **Default value:** No **Note:** This field was added in Version 2016.2, Service Update 5, and achieves the same functionality as **Type.ForecastErrorOutlierProcessingRule** = "Remove" and **Type.DemandOutlierProcessingRule** = "RemoveExcess".	String(Enum)	

Table 6.286: SafetyStockItem (Mfg) fields

Field name	Description	Data type	Key
ServiceLevel	The service level percentage that calculated safety stock recommendations for the part are meant to satisfy. For multi-echelon items this always specifies the probability of an order being fully satisfied (not stocking out), and for single-echelon items the interpretation of this field is configurable depending upon the **Type.ServiceLevelRule** setting as follows: • If set to "Cycle", this specifies the probability of an order being fully satisfied (not stocking out). • If set to "FillRate", this specifies the percentage of demand that should be satisfied on time. The service level specified is then converted to a service factor or multiplier for use in calculating safety stock. For example, the following shows estimated z-value scores that correspond to given service levels (assuming normally distributed demands and use of the "Cycle" rule) calculated using a standard normal table: **Service Level** / **Service Factor** 90% 1.282 91% 1.341 92% 1.405 93% 1.476 94% 1.555 95% 1.645 96% 1.751 97% 1.881 98% 2.054 99% 2.326 **Note:** To ensure meaningful results, a value between .50 and .99 should be provided (higher values results in higher safety stock levels being maintained but results in a decreased chance of a stock out). For example, in a typical configuration a value of .95 might be specified.	Quantity	

Table 6.286: SafetyStockItem (Mfg) fields

Field name	Description	Data type	Key
ServiceTime	The service or delivery time that this item should always be able to satisfy. This field is only applicable to multi-echelon safety stock items and defines the allowable time between when a customer orders an item and when the item is shipped. The value in this field should be expressed in terms of the Gregorian (everyday) calendar. Thus, calculated safety stock levels will ensure orders for the item can be satisfied within the number of calendar days specified here. For example, this might typically be set to 0 for parts held at customer-facing locations.	Quantity	
StandardDeviation Demand	A value representing the standard deviation of historical demands to use for the part in safety stock calculations. Applicable only to non-time phased items where **Type.StandardDeviationDemandRule** is set to "Manual" (used when there is limited historical data available but the demand parameters are known from some other means).	Quantity	
StandardDeviation LeadTime	A value representing the standard deviation of supply lead time to use for the part in single-echelon safety stock calculations. Applicable only when **Type.SupplyVariabilityRule** is set to "Manual" (otherwise, standard deviation of lead time is calculated from historical supply data).	Quantity	
TimePhased ReportCount	A value used to define the window of time over which time-phased safety stock calculations can be reported for this item. Expressed in units of **Type.IntervalsCalendar** and applied from the **RunDate.** Note that time-phased safety stock recommendations are made on **RunDate** as well as each subsequent date within the window in which there is a calculated change in the safety stock level. **Default value**: 1 (safety stock level is reported on **RunDate** only)	Integer	
Type	A reference to the control value that defines processing rules used for this safety stock item. For example, this reference sets the calendar used for safety stock calculations, specifies how standard deviation should be calculated, and defines how demand outliers should be processed. **Referenced table:** SafetyStockItemType	Reference	

SafetyStockItem table – calculated and set fields

The following describes the calculated and set fields in the **SafetyStockItem** table. For an introduction to this table, and descriptions of its input fields, see "SafetyStockItem table" on page 541.

Table 6.287: SafetyStockItem (Mfg) calculated fields

Field name	Description	Data type	Key
CalcAverageLead Time	Calculated historical average lead time for this item. The calendar this is reported in depends on the item's **Type.UseRollingLeadTimeDemand** setting as follows: • If **Y**, then expressed in **IntervalsCalendar** units. • If **N**, then expressed in **LeadTimeCalendar** units (but converted to IntervalsCalendar units when used in average demand profile calculations). **Note:** This field was added in Version 2016.2, Service Update 4.	Quantity	
RollingLeadTime DemandLastDate	Last date on which rolling lead time calculations for this item are valid. This is the latest date within the item's historical interval range for which there is a sufficient data range to determine demands within lead time. If the item has any records later than this date in the **SafetyStockHistoricalDemand** table, their **RollingLeadTimeQuantity** value set to -1.	Date	
SafetyStock HistoricalForecasts	Set of **SafetyStockHistoricalForecast** records that reference this item.	Set	

SafetyStockItemMapping table

The **SafetyStockItemMapping** table is used to map a safety stock item to one or more other "source" parts whose historical demand, historical supply, and/or future demand data should be included in calculations that determine the recommended safety stock level and reorder point for the item. The **Item** reference on this table identifies the **SafetyStockItem** that should have safety stock levels calculated, and the **SourcePart** reference identifies the part whose historical supply, historical demand, and historical forecast data is collected and used in generating those safety stock levels.

For example, source parts mapped to a safety stock item might be different revisions of the part defined on the **SafetyStockItem** record. Based on the mapping details, specific data from the source part is then combined with the records generated for the safety stock item in the **SafetyStockHistoricalDemand**, **SafetyStockHistoricalSupply**, and **SafetyStockItemFutureDemand** tables.

Table 6.288: SafetyStockItemMapping (Mfg) fields

Field name	Description	Data type	Key
Description	An optional description explaining the purpose of this item mapping.	String	
HistoricalDemand Category	The historical demand category for which the source part's historical demand data should be collected from the **HistoricalDemandActual** table. This reference is nullable, and can be left empty if historical demand data from the source part is not required. **Referenced table:** HistoricalDemandCategory	Reference	
HistoricalEndDate	The last date on which historical demand and/or supply data should be collected for the source part. This date should not be set later than the end of the historical collection interval for the safety stock item (can only be used to set an interval narrower than the one defined on the item itself). If left undefined, then the end of the safety stock item's historical collection interval is used instead.	Date	
HistoricalForecast Category	The historical category for which the source part's historical forecast data should be collected. When calculating the standard deviation of forecast error, historical forecast records for the source part in the **HistoricalDemandSeriesDetail** are collected only if they match this category through their **Series.Category** reference. This field is only applicable on items where Type.StandardDeviationDemandRule is set to "ForecastError". **Referenced table:** HistoricalDemandCategory (Nullable) **Note:** This field was added in Version 2014.4	Reference	
HistoricalStartDate	The first date on which historical demand and/or supply data should be collected for the source part. This date should not be set earlier than the start of the historical collection interval for the safety stock item (can only be used to set an interval narrower than the one defined on the item itself). If left undefined, then the start of the safety stock item's historical collection interval is used instead.	Date	
HistoricalSupply Category	The historical supply category for which the source part's historical supply data should be collected from the **HistoricalSupplyActual** table. This reference is nullable, and can be left empty if historical supply data from the source part is not required for the safety stock item. **Referenced table:** HistoricalSupplyCategory	Reference	

Table 6.288: SafetyStockItemMapping (Mfg) fields

Field name	Description	Data type	Key
Id	A unique string identifier for this record.	String	Yes
Item	A reference to the safety stock item. This identifies the specific part, and other details, associated with an item for which safety stock recommendations are being calculated. **Referenced table:** SafetyStockItem	Reference	Yes
IncludeFuture Demand	Indicates if future demand data from the source part should be used. Valid values are: • **N**—the source part's future demand data is not collected or used. • **Y**—the source part's future demand data is collected from the Demand table and included in bucketed totals for the item reported in the SafetyStockItemFutureDemand table.	Boolean	
Multiplier	A multiplier to be applied to the source part's historical and future demands. This value is used to increase or decrease the source part's demand quantities when reported for the safety stock item in the **SafetyStockHistoricalDemand** and **SafetyStockItemFutureDemand** tables. By default, this value is set to 1 (no multiplier is applied).	Quantity	
SourcePart	A reference to the source part whose historical demand, historical supply, or future demand data should be collected and used towards determining safety stock and reorder point for the safety stock item. If multiple categories of historical demand or supply data are required for a given safety stock item, then this can reference the same part as Item.Part (and different historical demand or supply categories chosen from what are set on the SafetyStockItem record) **Referenced table**: Part	Reference	

SafetyStockItemOutlier table

This table reports details related to outliers in historical data associated with a **SafetyStockItem**, analogous to **ForecastItemParametersOutliers**.

- Outliers are calculated based on the **SafetyStockItem** table and the results are stored in the **SafetyStockItemOutlierResult** and the **SafetyStockItemOutlierResultSummary** tables.
- The LeadTime in **SafetyStockHistoricalSupply** and the Quantity in **SafetyStockHistoricalDemand** will be corrected based on the data in this table.

This table was added in Version 2016.2, Service Update 5 to support the **Inventory Planning and Optimization** application.

Table 6.289: SafetyStockItemOutlier fields

Field name	Description	Data type	Key
Adjustment	The quantity of the outlier adjustment. This can be negative value.	Quantity	
Date	The historical date to which the outlier data reported on this record pertains. Each date reported here belongs to the item's **Type.IntervalsCalendar**. For example, dates might mark the beginning of a weekly or monthly period.	Date	Yes
Notes	Descriptive notes appended to this record.	Notes	
ProcessingRule	Specifies the historical data series to which the outlier belongs. Valid values are: • **Demand**—Indicates that the outlier belongs to the historical demand data series. • **Lead time**—Indicates that the outlier belongs to the lead time variability data series. This value is used for single-echelon only.	String(Enum)	Yes
SafetyStockItem	A reference to the **SafetyStockItem** record to which the outlier adjustments should apply. **Referenced table**: SafetyStockItem	Reference	Yes
UseWhen DetectingOutliers	Specifies whether to apply or ignore the **SafetyStockItem** record before detecting outliers when calculating **SafetyStockOutlierResult**. Valid values are: • **Y**—The historical data series for the **SafetyStockItem** record is used to detect outliers. • **N**—The historical data series for the **SafetyStockItem** record is not used to detect outliers. **Default value**: Y **Note:** This field has the same functionality as **ForecastItemParametersOutlier.ProcessingRule** = "All".	Boolean	

SafetyStockOverride table

The **SafetyStockOverride** table supports the Inventory Planning workbook. This table holds the results of both single-echelon safety stock calculations (recommendations for a single part) and multi-echelon safety stock calculations (recommendations for an end item and its related parts within a family).

Each record in this table contains a calculated safety stock quantity for a given part and date as taken from the SafetyStock worksheet in the Inventory Planning workbook. These results are copied using a worksheet copy command and are based on either an underlying transformation function (single-echelon parts) or an analytic as reported in the **MEIOStageResults** table (multi-echelon parts). Once

copied to this table, the calculated results are preserved and can be subsequently accessed again without the need to rerun the underlying analytic or function. As well, this table allows for overriding both single and multi-echelon safety stock recommendations as required. For example, if time phased safety stock calculations are produced, there might be a need to adjust the safety stock calculated in a particular month but accept all other recommendations.

The final results in the **SafetyStockOverride** table, including any specified overrides, can subsequently be used to overwrite or update the part's input safety stock values as provided in either the **TimePhasedSafety** table (for time-phased items) or **Part** table (for non time-phased items). This is done using a worksheet command in the Inventory Planning workbook. Note that a part's input values will only be only overwritten if their **SafetyStockPart.CopySafetyStock** value is set to "Y".

Table 6.290: SafetyStockOverride (Mfg) fields

Field name	Description	Data type	Key
AverageDemand	Average demand for the part. Corresponds to the AverageDemand field in the SafetyStockTimePhasedResult table. This field was added in Version 2016.2.	Quantity	
CalculatedService Level	The service level calculated using bounded safety stock. Corresponds to the CalculatedServiceLevel field in the SafetyStockTimePhasedResult table. This field was added in Version 2016.2.	Quantity	
CurrentQuantity	The current safety stock quantity, as determined and used by Netting calculations, that is effective for the part on the Date of this record.	Quantity	
Date	The date this safety stock recommendation applies to. For time-phased calculations, this reports the appropriate bucket date. For non time-phased calculations this always reports the RunDate.	Integer	
FutureDemand	Future bucketed demands for this part as determined by Netting calculations.	Quantity	
Id	A unique string identifier for this record (typically, generated based on workbook commands in the Inventory Planning workbook).	String	Yes
MaximumDays OfSupply	Maximum days of supply for the part. Corresponds to the **MaximumDaysOfSupply** field in the **SafetyStockTimePhasedResult** table. **Note:** This field was added in Version 2016.2.	Quantity	
MaximumQuantity	Maximum quantity for the part. Corresponds to the **MaximumQuantity** field in the **SafetyStockTimePhasedResult** table. **Note:** This field was added in Version 2016.2.	Quantity	

Table 6.290: SafetyStockOverride (Mfg) fields

Field name	Description	Data type	Key
MinimumDays OfSupply	Minimum days of supply for the part. Corresponds to the **MinimumDaysOfSupply** field in the **SafetyStockTimePhasedResult** table. **Note:** This field was added in Version 2016.2.	Quantity	
MinimumQuantity	Minimum quantity for the part. Corresponds to the **MinimumQuantity** field in the **SafetyStockTimePhasedResult** table. This field was added in Version 2016.2.	Quantity	
OriginalQuantity	Calculated safety stock quantity recommended for the part and effective date identified on this record. **Note:** If a part is configured as a single-echelon safety stock item, but it is subsequently brought into a multi-echelon family under another item, then its safety stock value as recommended by multi-echelon calculations is the one reported here.	Quantity	
Part	A reference identifying the part that the safety stock recommendations record pertains to, and containing the setting used to enable or disable automatic safety stock updates for the part. If the part is used in multi-echelon calculations, this reference also reports details of parameters used in recommending the safety stock level. Other details that are mostly relevant to multi-echelon safety stock calculations can also be accessed via this reference. **Referenced table:** SafetyStockPart	Reference	Yes
Quantity	This field can, optionally, be used to manually override the calculated safety stock recommendation. When values are copied to this table, this field is initially set to the same safety stock value as is reported in the **OriginalQuantity** field. However, when values in this table are used by the worksheet copy command to update safety stock values in either the **TimePhasedSafety** or **Part** tables, the value in this field is used. Therefore, any required adjustments or overrides to the safety stock level should be made in this field. The original recommendations are preserved in the **OriginalQuantity** field.	Quantity	
ServiceLevel	The service level calculated using unbounded safety stock. Corresponds to the **ServiceLevel** field in the **SafetyStockTimePhasedResult** table. **Note:** This field was added in Version 2016.2.	Quantity	

Table 6.290: SafetyStockOverride (Mfg) fields

Field name	Description	Data type	Key
StandardDeviation Demand	Calculated standard deviation of demand for the part. Corresponds to the S**tandardDeviationDemand** field in the **SafetyStockTimePhasedResult** table. **Note: StandardDeviationDemand** should be expressed in **Type.IntervalsCalendar**. **Note:** This field was added in Version 2016.2.	Quantity	
Unbounded Quantity	For single-echelon parts, this is the safety stock level without any bounds applied. For multi-echelon parts, this is the safety stock level required to meet the service level you have specified for the customer-facing part. If RapidResponse was able to calculate a safety stock level that meets your specified service level without violating safety stock bounds, this quantity matches the **OriginalQuantity** field. Corresponds to the **UnboundedQuantity** field in the **SafetyStockTimePhasedResult** table. **Note:** This field was added in Version 2016.2.	Quantity	

SafetyStockPart table

The **SafetyStockPart** table supports the Inventory Planning workbook. This table holds records pertaining to parts involved in single-echelon safety stock calculations (parts configured as safety stock items) and multi-echelon safety stock calculations (includes end-item assemblies configured as safety stock items as well as lower-level components brought into multi-echelon families under an end-item).

Most fields contained in this table report calculated parameters used in multi-echelon safety stock calculations. These details are based on values originally calculated for the **MEIOStage** and **MEIOStageResult** tables, and are copied to this table through a worksheet command in the Inventory Planning workbook. By copying the calculated results to this table, they can be saved and subsequently accessed again without the need to rerun the underlying analytic.

Additionally this table is used to set whether a part's recommended safety stock level, either from single or multi-echelon calculations, is used to overwrite (update) the part's existing input safety stock value. If the **CopySafetyStock** field is set to "Y" on the record for a given part, then the "CopySafetyStock" worksheet command in the Inventory Planning workbook will copy the recommended safety stock value (s) to either the **TimePhasedSafety** table (for time-phased results) or the **Part** table (for non time-phased results).

Table 6.291: SafetyStockPart (Mfg) fields

Field name	Description	Data type	Key
AverageDemand	Average historical demand calculated for the part in multi-echelon calculations. For customer facing end-items, this is based on demands placed directly on the part. For all lower level component parts, this is based on demand values propagated from higher level parts in the family. **Note: AverageDemand** should be expressed in **Type.IntervalsCalendar**.	Quantity	
AverageFuture Demand	Average of future bucketed demands for this part as determined by Netting calculations.	Quantity	
CopySafetyStock	Indicates if the calculated safety stock recommendations for the part, as reported in the **SafetyStockOverride** table, are used to overwrite (update) its existing input values defined in either the **TimePhasedSafety** or **Part** table. Valid values are: • **Y**—safety stock recommendations from either single or multi-echelon calculations are used to update the part's existing input values. This is typically done using a worksheet copy command run in the Inventory Planning workbook. • **N**—safety stock recommendations are not used to update existing input values.	Boolean	
CumulativeLead Time	Total time needed to process the part and all of its dependent parts in a multi-echelon family. Expressed in terms of the Gregorian (everyday) calendar.	Quantity	
Echelon	Indicates the level in the multi-echelon family where the part is located. For example, a customer-facing end item will have a value of 0, the stages/parts immediately below that a value of 1, the next level a value of 2, and so on.	Integer	
Family	A reference to the customer-facing end item at the head of the multi-echelon family (part) that this part belongs to. **Referenced table**: Part (nullable)	Reference	
Id	A unique string identifier for this record (typically, generated based on workbook commands in the Inventory Planning workbook).	String	Yes

Table 6.291: SafetyStockPart (Mfg) fields

Field name	Description	Data type	Key
IncomingService Time	Maximum service time found across all component parts directly below this one in a multi-echelon family. This is the maximum number of days within which the part can expect to have its immediate demands satisfied. Expressed in terms of the **MEIOReporCalendar** (on the **AnalyticsConfiguration** table).	Quantity	
LeadTime	Calculated time needed to process parts that are used in multi-echelon calculations This field relies on the part source's lead time, but is expressed in terms of the **MEIOReportCalendar** (on the **AnalyticsConfiguration** table) using the following expression: `PartSource.LeadTimeDate - RunDate`	Quantity	
OutgoingService Time	Recommended service time for the part (set and used by multi-echelon calculation. This is the maximum number of days within which the part guarantees it can satisfy the demands placed on it. For multi-echelon safety stock items, this is set to an input value specified on the safety stock item (if the input service time provided is greater than the cumulative lead time for the part, that cumulative lead time value is used instead). For all parts below those ends items in a multi-echelon family, this is calculated with the aim of minimizing total inventory holding costs. Expressed in terms of the **MEIOReporCalendar** (on the **AnalyticsConfiguration** table).	Quantity	
Part	A reference to the part the safety stock details on this record apply to. **Referenced table:** Part	Reference	Yes
PartSource	The primary part source for this part. This reference might be empty on records for parts belonging to multi-echelon families in certain situations. For example, if a buy part has multiple sources of the same priority as the primary source, then the part will have one record for each of those sources and an additional record with no part source reported (just the part itself). For more information about how part sources are reported in families, see "Create multi-echelon families" on page 1990. **Referenced table:** PartSource (nullable)	Reference	

Table 6.291: SafetyStockPart (Mfg) fields

Field name	Description	Data type	Key
SafetyStockItem	A reference to the safety stock item this record pertains to. This field is populated if the part has been configured as either a single-echelon or multi-echelon safety stock item (**ProcessingRule** field on SafetyStockItem will return either a value of either "SingleEchelon" or "MultiEchelon". If this record pertains to a lower level part brought into a multi-echelon family under a customer facing end item, then this reference is Null. **Referenced table:** SafetyStockItem (nullable) **Note: SafetyStockItem** should be expressed in **Type.IntervalsCalendar**.	Reference	
ServiceLevel	Service level used for this part when determining safety stock level. For parts configured as a safety stock item, this reports the service level provided as input on the **SafetyStockItem** record. For lower-level parts brought into multi-echelon families under a customer-facing end item, then the service level is typically set to that given on the item that brought it into the family. However, if a part is found under multiple items in a family, then this value is a weighted combination of those item's service levels.	Quantity	
StandardDeviation Demand	Standard deviation of historical demand calculated for the part.	Quantity	
StandardDeviation LeadTime	If this record pertains to a part in a multi-echelon family for much variable lead time is assumed, this field reports the calculated standard deviation of lead time for the part source.	Quantity	

Table 6.291: SafetyStockPart (Mfg) fields

Field name	Description	Data type	Key
Type	For parts involved in multi-echelon calculations, this identifies the part/stage type within the family (indicating how it was brought into the family). Valid values are: • **Buy**—a purchased part located at an internal stage in the family (**SafetyStockItem** reference will be Null). If the part has multiple sources of the same priority, there can be multiple records reported for the part (with different **Id** values). • **Customer**—a customer-facing end item where the part is referenced by a **SafetyStockItem** record with a **ProcessingRule** value of "MultiEchelon". • **InternalCustomer**—a customer-facing end item located at an internal stage in the family (the part is referenced by a **SafetyStockItem** record with a **ProcessingRule** value of "MultiEchelon"). For example, a safety stock item might have demand from external customers as well as demand from other internal parts (for example, as a transfer part). • **Make**—a manufactured part located at an internal stage in the family (**SafetyStockItem** reference will be Null). • **Transfer**—a part that is sourced from another site and located at an internal stage in the family (**SafetyStockItem** reference will be Null). Note that if a Transfer part has multiple sources, or if a given source supplies multiple parts with different transit times, there can be multiple records reported for the part (with different **Id** values). **Note:** For more information about the types of stages in a multi-echelon family, see "Create multi-echelon families" on page 1990.	String (Enum)	
UnitHoldingCost	The calculated cost of holding one unit of inventory for this part (based on the part's cost values and settings in **Part.InventoryHoldingRate** and **MultiEchelonSafetyStockRule.CostRule**). This value is required as input by multi-echelon calculations and used in determining the most cost effective placement of safety stock across the parts in a multi-echelon family.	Money	

SafetyStockPart table – calculated and set fields

The following describes the calculated and set fields in the **SafetyStockPart** table. For an introduction to this table, and descriptions of its input fields, see "SafetyStockPart table" on page 560.

Table 6.292: SafetyStockPart (Mfg) calculated fields

Field name	Description	Data type	Key
CalcFutureIntervals OfSupply	Calculated number of intervals of future demand (in terms of the **ReportCalendar**) that could be satisfied by the calculated safety stock on **RunDate** (where safety stock is taken from the **Quantity** field on the **SafetyStockOverride** table).	Quantity	
SafetyStock Overrides	Set of **SafetyStockOverride** records that reference this safety stock part.	Set	

SafetyStockRangeOfCoverage table

This table is used to define the range over which average demand is calculated for the purpose of calculating a part's recommended safety stock using the **SafetyStockItemType.TimePhasedProcessingRule** of "DaysOfSupplyForward" or "DaysOfSupplyBackward"

This table was added in Version 2016.2, Service Update 7.

Table 6.293: SafetyStockRangeOfCoverage fields

Field Name	Description	Data Type	Key
Count	The number of intervals over which average demand is calculated. For multi-echelon safety stock items, the intervals are days on the Everyday calendar. For single-echelon safety stock items, the intervals are days on the calendar specified in the **SafetyStockItemType.IntervalsCalendar** field.	Integer	
Offset	The start of the date range that average demand is calculated for, relative to the date for which safety stock is being computed. For multi-echelon safety stock items, this value is a number of days on the Everyday calendar. For single-echelon safety stock items, it is a number of calendar intervals on the calendar specified in the **SafetyStockItemType.IntervalsCalendar** field.	Integer	
Part	The part that the **Count** and **Offset** values apply to. **Referenced table**: Part	Reference	Yes

SafetyStockTimePhasedBounds table

This table supports the Inventory Planning workbook. It contains minimum and maximum safety stock bounds for parts and the dates on which these bounds start to apply. When safety stock bounds are used, RapidResponse does not recommend safety stock quantities outside of the specified bounds.

Safety stock bounds are specified either in terms of days of supply or quantity. The table can hold maximum and minimum values for both days of supply and quantity in the same record (four fields) but only one set (days of supply or quantity) can be used at a time. **SafetyStockItemType** settings control whether quantity bounds, days of supply bounds, or neither are used. For more information, see "Determining whether Days of Supply or Quantity bounds will be used" on page 1959.

A part can have multiple safety stock bounds records that become effective on different dates. The **Date** field in the **SafetyStockTimePhasedBounds** table specifies the date on which the safety stock bounds in that record start to apply. A bounds record remains effective until a bounds record with a later date overrides it.

If one or more records fall within a period, the one with the later date is used for that period.

This table was added in Version 2016.2.

Notes:

- When the **SafetyStockTimePhasedBounds** table contains records, safety stock is not allowed on artificial stages, even if **AnalyticConfiguration.AllowSafetyStockOnArtificialStages** is set to True.
- If a minimum bound is higher than the corresponding maximum bound, they cancel each other out, and are both treated as -1.

Table 6.294: SafetyStockTimePhasedBounds fields

Field name	Description	Data type	Key
Date	The date on which these bounds starts to apply.	Date	Yes
MaximumDaysOf Supply	Maximum days of supply for the part. **Default value**: -1. **Note:** Negative numbers are interpreted as positive infinity, and do not result in an upper bound being applied.	Quantity	
MaximumQuantity	Maximum quantity for the part. **Default value**: -1. **Note:** Negative numbers are interpreted as positive infinity, and do not result in an upper bound being applied.	Quantity	
MinimumDaysOf Supply	Minimum days of supply for the part. **Default value**: -1. **Note:** Negative numbers are interpreted as negative infinity, and do not result in a lower bound being applied.	Quantity	
MinimumQuantity	Minimum quantity for the part. **Default value**: -1. **Note:** Negative numbers are interpreted as negative infinity, and do not result in a lower bound being applied.	Quantity	

Table 6.294: SafetyStockTimePhasedBounds fields

Field name	Description	Data type	Key
Part	The part to which these bounds apply **Referenced table**: Part	Reference	Yes

SAP_MD04 table

The SAP_MD04 table contains stock requirement information, including supplies and demands for parts, created using the SAP MD04 transaction. This information is intended to be used for validating input data from SAP, and is not intended to be used for planning or decision making in RapidResponse.

The MD04 data consists of supply, demand, inventory, and allocation information for a part. This table can be used in worksheets to compare supply and demand values brought in to RapidResponse with the values as extracted directly from your SAP data source.

This table was added in RapidResponse 2016.2 Service Update 9.

Table 6.295: SAP_MD04 (Validation) fields

Field name	Description	Data type	Key
BAUGR_ PartNumber HigherLevel Assembly	The parent assembly that drives a dependent demand. This represents the BAUGR field in the SAP MDPS structure.	String	
Comments	Additional information about the supply and demand records.	String	
DAT00_ ReceiptDate	The date supply is planned to be available. This represents the DAT00 field in the SAP MDPS structure.	Date	
DAT01_ DeliveryDate	The date demand is planned to be delivered. This represents the DAT01 field in the SAP MDPS structure.	Date	
DEL12_ MRPElement Number	Production order numbers associated with supply and demand items, such as reservations, requirements, orders, and so on. This represents the DEL12 field in the SAP MDPS structure.	String	
DELET_ Scheduling Number	The scheduling line number for the purchase order, scheduling agreement, or sales order for this part. This represents the DELET field in the SAP MDPS structure.	String	
DELKZ_ MRPElement Type	The origin of the supply or demand item, such as a reservation, planned order, or production number. This represents the DELKZ field in the SAP MDPS structure.	String	

Table 6.295: SAP_MD04 (Validation) fields

Field name	Description	Data type	Key
DELNR_ MRPElement Data	The purchase requisition number, sales order number, planned order number, or purchase order number. This represents the DELNR field in the SAP MDPS structure.	String	
DELPS_ MRPElement Item	The reservation number of a dependent requirement of the production order. This represents the DELPS field in the SAP MDPS structure.	String	
Excluded	Whether this record is excluded from the comparison.	Boolean	
LIFNR_Vendor	The vendor number for a supply. This represents the LIFNR field in the SAP MDPS structure.	String	
MATNR_Material	The part number being analyzed. This represents the MATNR field in the SAP MDPS structure.	String	
MNG01_Recorded RequiredQuantity	The open quantity of a demand, supply, or inventory. This represents the MNG01 field in the SAP MDPS structure.	Integer	
STLKN_ ItemNodeNumber	Identifies the item node associated with this component in the BOM structure. This represents the STLKN field in the SAP MDPS structure.	String	
STLNR_ BillOfMaterial	The bill of material number identified in the production order. This represents the STLNR field in the SAP MDPS structure.	String	
STLTY_ BOMCategory	The bill of material type for the order. This can be one of the following values: • **M**—Material BOM • **K**—Order BOM This represents the STLTY field in the SAP MDPS structure.	String	
STPOZ_Counter	The item counter associated with the component in the bill of materials. This represents the STPOZ field in the SAP MDPS structure.	String	
WERKS_Plant	The site the part is present in. This represents the WERKS field in the SAP MDPS structure.	String	
Part	The part the supply and demand record is defined for. **Referenced table:** Part	Reference	

Table 6.295: SAP_MD04 (Validation) fields

Field name	Description	Data type	Key
Site	The site the supply and demand record is defined for. **Referenced table:** Site	Reference	

ScheduledReceipt table

The **ScheduledReceipt** table contains supply for a single part that has an assigned due date. Examples of supplies are: purchase orders and manufacturing orders.

Table 6.296: ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
ActionCode	The action code for an order line brought in from the Real-time Integration Service and included in a supplier collaboration process. This field is taken from the IDOC message and can contain the following values: • **Added**—Records defined by the message are added to the RapidResponse database. If the specified records already exist, the message fails. • **Changed**—Records defined by the message are modified, or inserted if they do not already exist in the RapidResponse database. • **Cancelled**—Records defined by the message are cancelled, which modifies the status of the order records. • **Deleted**—Records defined by the message are deleted. • **NotChanged**—Records defined by the message are not modified, so no actions are taken and the record is ignored. • **Locked**—Records defined by the message are locked, and cannot be modified. This field is in the **SupCollab** namespace. This field maps to the ACTION field in the E1EDP01 segment of the IDOC message.	String	
ActualDockDate	The actual date this supply arrived at the receiving dock, which is used in historical reporting. This field is in the **Solutions** namespace. **Note:** This field was added in the Version 2016.2, Service Update 5.	Date	

Table 6.296: ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
ActualShipDate	The actual date this supply was shipped from the supplier, which is used in historical reporting. This field is in the **Solutions** namespace. **Note:** This field was added in the Version 2016.2, Service Update 5.	Date	
AllotmentOverride	A reference to the allotment override reserving component supply to this work order. The reserved supply is allocated to any work order(s) referencing the allotment override before it can be made available to other orders. **Referenced table:** AllotmentOverride (Nullable)	Reference	
AnchorDate	The anchor date associated with this supply. When the BOMType.DateRule is set to 'AnchorDate', the anchor date is used instead of the order start or due date in bill effectivity. If bill effectivity is based on anchor date, material allocations for an order are frozen despite subsequent rescheduling of the order. Anchor date logic is ignored if the AnchorDate equals d'Undefined' or if BOMType.DateRule is not 'AnchorDate'. **Default value**: Undefined	Date	
BOMAlternate	A reference to the alternate BOM used by this scheduled receipt. When Netting logic performs explosion calculations, only components that have **BillOfMaterial.Alternate** matched to either the value in this field or the first value in the **BOMAlternate** table (that is, common components) can potentially create new allocations for this scheduled receipt. In cases where this value differs from the value in **PartSource.BOMAlternate,** the value in this field is used, and the part source value is ignored. For more information about alternate BOMs, see "Alternate BOM calculations" on page 1759. **Referenced table**: BOMAlternate **Note:** This field is ignored for a given scheduled receipt unless **Order.Type.Source** = 'Make', and **Status.State** is set to either 'NotReleased', 'Planned', or 'ReleasedButNotAllocated'.	Reference	

Table 6.296: ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
BuildStatus	Records whether an order was scheduled to completion. Valid values are: • **No_Build**—the order was not scheduled to start within the scheduling horizon. • **Partial**—the order was started, but not completely scheduled (finished) in the scheduling horizon. • **Complete**—the order was completely scheduled in the scheduling horizon. **Note:** This is an obsolete field. **Default value**: No_Build	String (Enum)	
BuyerCommit	For an order that is undergoing a supplier collaboration process, whether the buyer has committed to the order. A buyer can commit only after the supplier has committed. Valid values are: • **Y**—The buyer has committed to the order. • **N**—The buyer has not committed to the order. This field is in the **SupCollab** namespace.	Boolean	
ConfirmDate	For an order line committed to by a supplier, the due date of the confirmed order. This field provides data for an IDOC message response or order change. This field is in the **SupCollab** namespace. This field maps to the EDATU field in the E1EDP01.E1EDP20 segment of the IDOC message.	Date	
ConfirmQty	For an order line committed to by a supplier, the quantity the supplier has confirmed. This field provides data for an IDOC message response or order change. This field is in the **SupCollab** namespace. This field maps to the WMENG field in the E1EDP01.E1EDP20 segment of the IDOC message	Quantity	
ConfirmationDateTime	For an order line committed to by a supplier, the date and time the supplier confirmed the order. This field provides data for an IDOC message response or order change. This field is in the **SupCollab** namespace. The Date component of this field maps to the EDATU field in the E1EDP01.E1EDP20 segment of the IDOC message. The Time component of this field maps to the EZEIT field of the E1EDP01.E1EDP20 segment of the IDOC message.	DateTime	

Table 6.296: ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
CurrentOperation	When a routing has been partially completed, this field is used to start the processing of the routing at an operation other than the first operation. When backward scheduling the order, all operations remaining will be scheduled relative to the due date of the order. When forward scheduling the order, all operations remaining will be scheduled relative to the MRP RunDate. This field is used by the Capacity Requirements Planning analytic. If this analytic is not being used, this field can be left blank. **Default value**: 0 **Note:** This field is applicable to operations defined through the **Operation** table only (for operations configured through the **CRPOperation** table, the **CRPOperationState** table should be used to indicate the current operation).	Integer	
CurrentOperation CompleteQuantity	The number of units completed by the current operation. The difference between the scheduled receipt's Quantity and this field indicates what remains to be processed by the current operation. This field is used by the Capacity Requirements Planning analytic. If this analytic is not being used, this field can be left blank. **Default value**: 0 **Note:** This field is applicable to operations defined through the **Operation** table only (for operations configured through the **CRPOperation** table, the **CRPOperationState.CompleteQty** should be used to indicate the amount of the current operation that is complete).	Integer	
DockDate	The date this supply is supposed to be delivered to the manufacturer's dock. Analytics will calculate from DueDate if DockDate is 'Undefined'.	Date	
DockToStock LeadTime	The time needed to move materials from the receiving dock to available inventory. This value is used in lead time calculations when the part source's lead time is overridden by the scheduled receipt (as set by the values on **SupplyStatus.LeadTimeOverride** and **SupplyType.LeadTimeRule**).	Quantity	
DrawingRevision	This field is used for internal purposes in RapidResponse. **Note:** This field is obsolete.	String	

Table 6.296: ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
DueDate	The date the order is planned to be in stock. **Default value**: Future	Date	
ExpiryDate	The date on which the material in this supply expires (is no longer usable). If a value is provided in this field, it is also reported in the **CalcExpiryValue** field (as long as **PartType.ExpiryRule** is not set to "Ignore"). Otherwise, RapidResponse calculates the **CalcExpiryValue**. For guidelines about when to populate this field, see "Providing an expiry date for scheduled receipts" on page 1605. **Default value:** Undefined	Date	
ExpiryStartDate	The date on which the material in this supply starts to expire. If a value is provided in this field, it is also reported in the **CalcExpiryStartDate** field (as long as **PartType.ExpiryRule** is not set to "Ignore"). Otherwise, if a value is not provided in this field, then **CalcExpiryStartDate** is either determined from an analytic calculation or set to "Future" (depending on the configured expiry rules and types). This field is most typically used with expiry parts that are designated as limiting components. **Note:** This field was modified in Version 2016.2, Service Update 8 (previously, this was a calculated field and there was no way to provide it as input).	Date	
FixedLeadTime	The time needed to produce the material (independent of order quantity). This value is used in lead time calculations when the part source's lead time is overridden by the scheduled receipt (as set by the values on **SupplyStatus.LeadTimeOverride** and **SupplyType.LeadTimeRule**.	Quantity	
FocusIndicator	Flags an order to be reported with separate statistics. Focus orders are not scheduled differently; just their statistics are reported separately. Valid values are: • **Y** • **N** **Default value**: N **Note:** This field is obsolete. As a result, set this field to N.	String	

Table 6.296: ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
InputModel	The model that is associated with this scheduled receipt. Based on the **SupplyStatus.ModelUsage** setting, either this model or the default model (the None model) is effective for the receipt. The actual usage of the receipt's effective model in analytic calculations is determined by the setting in the **Part.MUEPoolNettingType.ModelRule** field. This also depends on the Model-Unit Effectivity capability having been enabled. **Referenced table:** Model	Reference	
InputPool	The pool to which this scheduled receipt belongs. This field supports inventory pooling, and is used only when **Part.MUEPoolNettingType.PoolRule** is set to either "Net" or "Optional". If this field is left Null, then the pool from **Order.Pool** is used instead. Therefore, this field is typically used when the pools applicable to supplies more naturally correspond to individual line items rather supply orders, or when there is a need to inject pool information at the component level from scheduled assembly supply. **Referenced table:**Pool (Nullable) **NOTE**: This field was added in Version 2016.2, Service Update 19.	Reference	
LastModified	The date on which the order was last updated with data from the Real-time Integration Service. This field is also used to determine which order lines are no longer applicable. This field is in the **SupCollab** namespace.	Date	
Line	A unique identifier associated with each ScheduledReceipt record with the same Order.Type and Order.Id. **Default value**: blank string	String	Yes
LineValue	The total price of the order line brought in from the Real-time Integration Service and included in a supplier collaboration process. This field is taken from the IDOC message. This field is in the **SupCollab** namespace. This field maps to the NETWR field of the E1EDP01 segment of the IDOC message.	Money	
Order	A value that determines the processing policies of this scheduled receipt. **Referenced table:** SupplyOrder **Reference Syntax:** Order.Type, Order.Id, Order.Site	Reference	Yes

Table 6.296: ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
OrderPriority	The priority associated with this order when **SupplyStatus.PrioritySource** is set to "FromInput". Ignored for all other PrioritySource values (unless the Netting analytic does not use this receipt to satisfy any demands). **Referenced table:** OrderPriority **Note:** The effective order priority on scheduled receipts is reported in the **EffOrderPriority** field.	Reference	
OriginalDueDate	The date on which the order was promised or contracted to be due. This is the DueDate that was originally on the ScheduledReceipt when the allocations were made. This may be different than the due date because the due date reflects the achievable target due date. **Default value**: Undefined	Date	
OriginalQuantity	This field should only be populated if it is used to calculate the **Allocation.EffQuantity** field (that is, if RapidResponse's mechanism of updating the Allocation every time there is a quantity change on the scheduled receipt is used). If populated, this field must contain the same value as the **Quantity** field. Imported allocations will have the **EffQuantity** (quantity that is used in netting calculations) recalculated based on the **ScheduledReceipt.OriginalQuantity * BillOfMaterial.QuantityPer**; that is, the imported **Allocation.RemainingQuantity** is not used in netting calculations. **Note:** For more information about automatic allocation adjustments, see "Automatic allocation adjustment" on page 1399).	Quantity	
OriginalRecordId	Identifies records that have been sent to your enterprise data sources in a closed-loop operation. This is a concatenation of the date the closed-loop operation was performed and the RecordId value for the record. When data is next updated, this value is compared to the new ScheduledReceipt records and ensures the records are not double-counted. The RecordId value is a number representing the sequence a record was created in. Each additional record added to the table increments the RecordId by one, and RecordId values are not reused when records are deleted. For more information about RecordId, see the *RapidResponse Resource Authoring Guide*. This field is in the **Solutions** namespace.	String	

Table 6.296: ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
Part	Part for which this ScheduledReceipt exists. This field references the Part table. **Referenced table:** Part **Reference Syntax:** Part.Name, Part.Site	Reference	
PreShipLT	The time needed by the source to collect the inventory and prepare it for shipment. This value is used in lead time calculations when the source's lead time is overridden by the scheduled receipt (as set by the values on **SupplyStatus.LeadTimeOverride** and **SupplyType.LeadTimeRule)**.	Quantity	
PreviousQty	For an order line that was changed by an update from the Real-time Integration Service, the line's quantity before the change. This field is taken from the IDOC message. This field is in the **SupCollab** namespace. This field maps to the AMENG field of the E1EDP01.E1EFP20 segment of the IDOC message.	Quantity	
Priority	Defines the priority of the Purchase Order. Valid values range from one to five. One represents the highest priority. Specify **X** for this field which represents no expressed priority. **Note:** This field is only applicable to RapidResponse legacy applications.	String (Enum)	
Processed	For an order brought in by the Real-time Integration Service and undergoing a supplier collaboration process, whether the order has been committed to by the supplier, accepted and committed to by the buyer, and the confirmation returned to your enterprise data source. Valid values are: • **Y**—The supplier has committed to the order, the buyer has accepted and committed to the order, and the order confirmation has been sent to your enterprise data source. • **N**—Either the supplier has not committed to the order or the buyer has not accepted or committed to the order. This field is in the **SupCollab** namespace.	Boolean	

Table 6.296: ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
ProtectQuantity	Indicates whether the value in the Quantity field is modified when data is edited in a grouped worksheet. This field is used in the Advanced Data Editing dialog box as part of the expression that determines which records are not edited when a grouped worksheet is edited. Valid values are: • **Y**—the Quantity cannot be modified in summarized worksheets. • **N**—the Quantity can be modified. For more information, see "Protect a record" in the *RapidResponse Resource Authoring Guide*. **Default value**: N	Boolean	
Quantity	The total amount that will be available before testing (for example, before applying yield and accounting for any co-product or by-product supply). **Default value**: 0	Quantity	
ReviewedDateTime	The last time this supply had its status reviewed (by its supplier). **Default value**: Undefined	Date Time	
Routing	The routing for the order. It is a reference to the Routing table through the Routing.Id field. **Note:** This field is used by the Capacity Requirements Planning analytic. If this analytic is not being used, a value must still be entered in this field (in this case, it can be set to "None"). **Referenced table:** Routing	Reference	
SavedPriority	Duplicates OrderPriority, load with same data as OrderPriority. Not used by RapidResponse analytics, but might be used by applications, such as custom applications. **Referenced table:** OrderPriority	Reference	
SchedulePriority	A factor used in prioritizing and scheduling orders on work centers when due dates are the same. **Note:** This field is obsolete.	Integer	
SegmentQualifier	For an order line committed to by a supplier, identifies the order total IDOC segment for a shipment notification. This field is taken from the IDOC message. This field is in the **SupCollab** namespace.	String	

Table 6.296: ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
ShipTo	Location to which this order is to be delivered. **Note:** This field is obsolete and only applicable to RapidResponse legacy applications.	String	
Shipment	The shipment that contains (or is planned to contain) this supply. **Referenced table:** Shipment (this reference is nullable in new installations of RapidResponse 10.1 and later).	Reference	
StartDate	The date that the order is scheduled to be released to the supplier or shop floor. **Note:** If the StartDate is undefined, this value is calculated. **Default value**: Undefined	Date	
StartUnit	The unit number (serial number) of the first unit in this receipt. **Default value**: -1	Integer	
Status	Processing rule modifiers on a per line basis used in conjunction with the Order.Type. A Firm status on a WorkOrder will generate NewAllocations, but Open ones already have Allocations. **Referenced tables:** SupplyStatus	Reference	
SupplierCommit	For an order that is undergoing a supplier collaboration process, whether the supplier has committed to the order. A supplier can commit only if the quantity and due date for the order have been accepted. Valid values are: • **Y**—The supplier has committed to the order. • **N**—The supplier has not committed to the order. This field is in the **SupCollab** namespace.	Boolean	
SupplierResponse	For orders undergoing a supplier collaboration process, the supplier's response to the order's proposed quantity and delivery date. Valid values are: • **Accepted**—The supplier accepts the order with the proposed quantity and delivery date. • **Changed**—The supplier accepts the order with a different quantity or delivery date. • **Rejected**—The supplier has rejected the order. This field is in the **SupCollab** namespace.	String	

Table 6.296: ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
TotalQuantity	The total quantity of parts this scheduled receipt includes (Quantity is the balance remaining, so the difference is received + scrap.)	Quantity	
Transaction Sequence	The sequence of the scheduled receipt. This value is assigned to transaction sequence on resulting dependent demands. If dependent demands have the same order priority and the value of **MaintainCommitments** is set to 'Y' for the dependent demands part, then supplies will be allocated by transaction sequence (smallest to largest). **Note:** On startup, the server checks the maximum value for a transaction sequence number and if the value is greater than 0x30000000 hex (or 805306368 decimal), it will reset the sequence number back to zero and re-sequence all the ScheduledReceipt and IndependentDemand records.	Integer	
TransitTime	The number of days the order must be shipped prior to it being available for use in manufacturing. This value is used in lead time calculations when the source's lead time is overridden by the scheduled receipt (as set by the values on **SupplyStatus.LeadTimeOverride** and **SupplyType.LeadTimeRule**).	Quantity	
Unconstrained Quantity	The quantity of this supply that has had constraint applied to it and does not require any more constraint. The constrained quantity is calculated, depending upon SupplyStatus.TargetAccum, as Quantity or TotalQuantity - UnconstrainedQuantity. A result of 0 or a negative value results in no load on the constraint. Values of UnconstrainedQuantity < 0 are ignored. UnconstrainedQuantity is ignored unless the scheduled receipt is limited by constraint.	Quantity	
UnitPrice	The unit price to be used for this order. In cost calculations, UnitPrice is assumed to represent material costs only. If UnitPrice is less than or equal to zero, use PartSource.EffUnitCost less labor and overhead costs for material costs instead. Labor and overhead costs are always calculated from PartSource fields.	Money	
VarLeadTime	A variable portion of lead time dependent on order quantity (this value is multiplied by the scheduled receipt quantity). This value is used in lead time calculations when the part source's lead time is overridden by the scheduled receipt (as set by the values on **SupplyStatus.LeadTimeOverride** and **SupplyType.LeadTimeRule**).	Quantity	

ScheduledReceipt table – calculated and set fields

The following describes the calculated and set fields in the ScheduledReceipt table. For an introduction to this table, and descriptions of its input fields, see "ScheduledReceipt table " on page 569.

Table 6.297: Calculated ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
AvailableDate	The date this supply is likely to be available based on materials, order status, and constraint.	Date	
AvailableStartDate	The date of the earliest constraint allocated to this supply (ship date or start date) converted to a start date. If incremental availability calculations are turned off, then all component materials must be available before constraint can be allocated. If incremental availability calculations are turned on, then only some set of component materials must be available before constraint can be allocated.	Date	
CalcExpiryDate	The calculated date on which the supply in this scheduled receipt will expire (is no longer usable). This field is calculated as follows: • If the **ExpiryDate** field is not "Undefined", then it is to the **ExpiryDate** value . • If the **ExpiryDate** field is "Undefined" and **PartType.ExpiryRule** is "Dependent", then it is set to the earliest calculated expiry date on any component supply allotted to this order. • If **ExpiryDate** is "Undefined" and **PartType.ExpiryRule** is "Self" or "SelfReset", then it is calculated by adding the value in **PartSource.IntervalsToExpiry** (expressed in terms of the part's expiry calendar) to either the supply's available date, dock date, or stock date (as determined by the setting in **PartSourceType.ExpiryDateRule**). • If **PartType.ExpiryRule** is "Ignore", then it is always set to "Future" regardless of any other field settings.	Date	

Table 6.297: Calculated ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
CalcExpiryStart Date	The calculated date on which this supply starts to expire. This date is rolled up the product structure through parts using a "dependent" expiry type. For assembly parts with a **PartType.ExpiryRule** setting of "DependentStart", the earliest rolled up **ExpiryStartDate** from supply of a limiting component is then used to start expiry date calculations for the assembly supply. This field is populated as follows: • If an input value is found in **ExpiryStartDate**, then it is always used here (assuming the part's **PartType.ExpiryRule** is not set to "Ignore"). • If no input value is found and the part is designated as a limiting component (that is, the **ExpiryType.ProcessingRule** is set "LimitingComponent), then the component supply's due date, dock date, or start date is used (determined by **PartType.ExpiryDateRule**) • If no input value is found and the part has a **PartType.ExpiryRule** of "DependentStart" with limiting components in its structure, then the earliest expiry start date rolled up from a limiting component supply is sued. • Otherwise, set to "Future". **Note:** This field was added in Version 2016.2, Service Update 6. Previously, the calculated expiry start date was reported in the **ExpiryStartDate** field, however that field has been changed to an input field which can be used to specify a date on which expiration calculations should begin.	Date	
CalcRequestStart Date	The date on which work should start on this supply in order to meet the earliest request date on any driving independent demand it satisfies. Based on the original **RequestDate** exploded down from the driver **IndependentDemand** record and adjusted by lead time at each level in the product structure (if the supply directly satisfies an independent demand itself, then this is just the **RequestDate** adjusted by the part's lead time). If the driver demand is not an independent demand, or has an undefined **RequestDate**, then this is the date on which work should start on this supply in order to meet the due date on the driver.	Date	
CalcStartDate	The order start date as calculated by netting, including allowance for constraint. If StartDate is not d'undefined', StartDate + (Resched Date - OriginalDueDate Part.PlanningCalendars.TimeUnits) Part.PlanningCalendars.TimeUnits Otherwise, if StartDate is d'undefined', CalcStartDate is ReschedDate (dock date) converted to a start date.	Date	

Table 6.297: Calculated ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
Constraint	The Constraint that has insufficient remaining capacity to make this supply available for its MaterialAvailableDate. If this supply is not late, this field is empty. **Referenced table**: Constraint	Reference	
CostOfGoodsSold	The total rolled-up costs of goods sold from all component supplies used to fill this order. This field summarizes the date-specific cost values reported in the **ScheduledReceiptCost** table and described on page "ScheduledReceiptCost table" on page 1178.	Money	
DemandDate	The date of the earliest demand that netting matches with this supply. DemandDate can differ from RecommendedDate for non-reschedulable supplies, if constraint limitations result in pre-build recommendations, and for parts that use safety lead time. **Note**: The date reported in this field must belong to the part's **PlanningCalendars.TimeUnits** calendar. If this supply is matched to an independent demand with a due date that does not fall on the part's **TimeUnits** calendar, it is adjusted back to the previous **TimeUnits** interval before being reported in this field.	Date	
DockDateFrom Start	The order dock date after adjustment based on any calendar rounding applied when determining the calculated start date. For example, parts that use "cumulative" lead time might end up with an earlier dock date from start based on rounding between time units, transit, ship, and lead time unit calendars. **Note:** This field was added in Version 2016.2	Date	
DueDateFromStart	The order due date after adjusting for any calendar rounding applied when determining the calculated start date. For example, parts that use "cumulative" lead time might end up with an earlier due date from start based on rounding between time units, transit, ship, and lead time unit calendars. **Note:** This field was added in Version 2016.2	Date	

Table 6.297: Calculated ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
EarliestExpiryDate	The earliest date that any supplies being used to satisfy dependent demands from this receipt may expire. Typically, this is determined from the latest **EarliestExpiryDate** found on any demand that Netting calculations determine this supply will satisfy. Otherwise, if there are no consuming demands, this value is calculated by adding the number of expiry calendar intervals defined in **Part.MinimumShelfLife** to the supply due date. For non-expiry parts (**PartType.ExpiryRule is** set to "Ignore"), this field always reports "Past".	Date	
EffDockDate	The date this supply is supposed to be delivered to the receiving dock. If the supply has a valid delivery date, then EffDockDate is calculated from that. Otherwise, if DockDate is not 'Undefined', then equals DockDate. Otherwise, is calculated from DueDate.	Date	
EffDueDate	The date this supply is supposed to be available for use. If the supply has a valid delivery date, then EffDueDate is calculated from that. Otherwise, if DueDate is not 'Undefined', then equals DueDate. Otherwise, is calculated from DockDate.	Date	
EffectiveUnitPrice	The sum of all costs (material, labor and overhead) to produce this receipt, reported in stock units of measure. If the UnitPrice > 0, this value is calculated as `UOMConversion(UnitPrice + max(LaborCost, 0) + max(OverheadCost, 0) + max(OverheadCost2, 0)`. Otherwise, it is set to PartSource.EffUnitCost. Currency conversions on this field use the **EffDueDate** field's conversion rate.	Money	
EffOrderPriority	The effective order priority for this scheduled receipt. Depending on the setting in **SupplyStatus.PrioritySource**, this field either uses the OrderPriority value provided on the scheduled receipt record or is dynamically calculated based on the priorities of the demands satisfied by the receipt in netting calculations (these may not necessarily be the demands that capable-to-promise calculations later allocate to the scheduled receipt). For parts where priority is relevant (for example, when **PartType.CommitLevel** is set "High") , this value is used when allocating limited materials and constraint to an order, and is also propagated down to its dependent components. For more information about how order priority on scheduled receipts is calculated and used, see "Priorities on scheduled receipts" on page 1788. **Referenced table:** OrderPriority	Reference	

Table 6.297: Calculated ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
EffQuantity	The quantity of this receipt that remains to be received into inventory, in inventory units of measure. This value is calculated by taking the Quantity and subtracting InTransitConsumedQuantity (if applicable), then adjusting by yield/scrap, considering any co-product or by-product supply, and applying unit of measure. If **SupplyType.ProcessingRule** is set to "Ignore" or **SupplyStatus.State** is set to "Historical", or the part's **PartType.ProcessingRule** is set to "Ignore", this field will always return 0 (zero). In such cases, none of the receipt can be used to cover demand by Netting.	Quantity	
EffShipDate	The date this supply was or should be shipped based on EffDueDate.	Date	
EffStartDate	The date the order was or should be started, calculated from DueDate, DockDate, and StartDate.	Date	
EstimatedExpiry Date	The date that the Netting analytic calculates this supply will expire. Used to determine which demands this receipt can potentially be used to satisfy (supply is only eligible for use if it is on or before the demand's **EarliestExpiryDate**). Note that this date might be different than the actual expiry date reported in **CalcExpiryDate** which takes supply availabilities into account. If a value is provided in the **ExpiryDate** field, then it is used here. Otherwise, calculated by adding the number of expiry calendar intervals defined in **PartSource.IntervalsToExpiry** to either the **EffectiveDueDate**, **StartDate,** or **DockDate** (as determined by the setting in **PartSourceType.ExpiryDateRule**). Non-expiry parts, where **PartType.ExpiryRule** is set to "Ignore", always return a value of "Future".	Date	
ExpiringQuantity	The amount of this scheduled receipt that will not be used before it expires (reaches its **CalcExpiryDate**).	Date	
FirstAvailableDate	The date the first portion of this supply should be available based on materials, order status, and constraint. This value is different than the AvailableDate field in cases where the order has been split due to incremental availability of component materials or constraint consumption in multiple periods.	Date	

Table 6.297: Calculated ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
InTransit ConsumedQuantity	The amount of the scheduled receipt that has been consumed (reduced) by related in-transit scheduled receipts. This value is reported in supplier units of measure, and is not adjusted for yield. For more information about in-transit scheduled receipts, see "In-transit scheduled receipts" on page 1734.	Quantity	
MaterialAvailable Date	The date this supply is available calculated from MaterialStartDate.	Date	
MaterialStartDate	Date when all components are available and this order can be started. For work orders, this is based only on component availability. For purchase orders, this is the same as CalcStartDate.	Date	
Model	The model used when netting this record. Either the **Model** value referenced in the **InputModel** field or the default **Model** value ("None") is returned as determined by the settings in **Part.Type.MUEPoolNettting.ModelRule** and **SupplyStatus.ModelUsage.** The following criteria is used: • If **ModelRule** is set to "Net" or "NetWithoutForecast" and **ModelUsage** is set to "Normal", then the **InputModel** value is returned. • If **ModelRule** is set to "Net" or "NetWithoutForecast" and **ModelUsage** is set to "Ignore", then the default **Model** ("None") is returned. • If **ModelRule** is set to "ExplodeOnly" or "Ignore" then the default **Model** ("None") is returned. • If the optional Model-Unit Effectivity capability is not enabled, then the default model ("None") is always returned regardless of field settings. **Referenced table:** Model	Reference	
NeedQty	Quantity of the supply actually needed to cover the demand. This field is expressed in stock units, and inflated to cover yield.	Quantity	
NewProcessCost	Standard labor and overhead cost of planned orders to complete this order. Currency conversions on this field use the **EffDueDate** field's conversion rate.	Money	
NewPurchasesCost	Cost of new purchases required in order to complete this order (through all levels of the bill). Currency conversions on this field use the **EffDueDate** field's conversion rate.	Money	

Table 6.297: Calculated ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
OnTimeQuantity	The quantity of this supply that could be completed on or before its ReschedDate (considering materials only) if it was possible to split the order. This value accounts for components available in time to apply lead time to complete the assembly for its ReschedDate including supplies and InKit materials.	Quantity	
ParameterDate	The date that was used to determine which time-phased parameter values are applicable to this supply (compared against the **EffectiveInDate** values on certain applicable tables). For example, if using time-phased yield then the **TimePhasedYield** record effective for the part source on this date determines the yield factor. Also, applies to time-phased **SourceConstraint** records as well as time-phased lead time logic (records in the **TimePhasedPartSourceLeadTime** and **TimePhasedSourceLeadTime** tables). Depending on the status of the scheduled receipt, this date is set as follows: • For non-reschedulable receipts, the **DueDate** is used (set to "Past" if the **DueDate** is left undefined). • For reschedulable receipts, the **ReschedDate** is typically used (or the date from the first attempt at rescheduling the supply). However, if **SupplyStatus.AllowLatePlan** is set to "Y" and the **ReschedDate** then moves past the demand's due date, that demand due date is used instead. Additionally, if allotment overrides are used this is set to the receipt's effective stock date instead. And for part's that have **PartType.CommitLevel** set to "High", this date will not always correspond to **ReschedDate** (but will always correspond to the period from which the effective quantity of the receipt is calculated). **Note:** This field was added in Version 2016.2, Service Update 12.	Date	
PartSource	The PartSource record that corresponds to this supply. Used by calculations for Transfer (explosion), Ongoing, and Yield processing. For details about how this field is calculated, see "Part sources for scheduled receipts" on page 1389. **Referenced table:** PartSource	Reference	
PartSupplier	A reference to the entry in the PartSupplier table, if any, that has the same part and supplier as this ScheduledReceipt record (Part and Order.Supplier). **Referenced table**: PartSupplier	Reference	

Table 6.297: Calculated ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
Pool	The pool used when netting this supply. The value returned here is affected by the **Part.MUEPoolNettingType.PoolRule** setting as follows. • If **PoolRule** is set to "Net" or "Optional" and the **InputPool** reference on this line item is populated, then that referenced pool is used. • If **PoolRule** is set to "Net" or "Optional" and the **InputPool** reference on this line item is Null, then the pool referenced by **Order.Pool** is used (from the supply order). • If **Part.MUEPoolNettingType** is "Ignore", "Forecast", or "ForecastOptional", the part's common pool, from the **Part.PlanningCalendars.CommonPool** reference, is always used. **Referenced table:** Pool	Reference	
RecommendedDate	This field considers rescheduling rules and expedite limits. It reports the date where Netting puts the scheduled receipt for the purpose of demand provision. If the supply is "RecommendOnly", it will report the date where netting wanted it without actually moving it there. Note that dependent demands are not generated with reference to this date.	Date	
Recommended DockDate	The dock date based on RecommendedDate.	Date	
ReschedDate	This field considers rescheduling rules and expedite limits. It reports the date where Netting puts the scheduled receipt in order to generate dependent demands. If the supply is "Reschedulable", then this field gives the same date as RecommendedDate; otherwise, it is the same as the DueDate.	Date	
ReschedDockDate	The dock date based on ReschedDate.	Date	
ShipDate	The date this supply was or should be shipped based on ReschedDate.	Date	
ShipDateFromStart	The order ship date after adjustment based on any calendar rounding applied when determining the calculated start date. For example, parts that use "cumulative" lead time might end up with an earlier ship date from start based on rounding between ship and lead time unit calendars. **Note:** This field was added in Version 2016.2	Date	

Table 6.297: Calculated ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
StockUnitQuantity	Represents the supply quantity in inventory unit of measure (UOM), including any reduction for InTransitConsumedQuantity, and without applying yield or scrap factors. This field also does not account for the settings in either the SupplyStatus or SupplyType tables (and thus can return a positive value for orders that are ignored by Netting and have EffQuantity = 0). **Note**: **SupplierUOM** applies to **StockUnitQuantity**.	Quantity	
TaskNeedDate	The earliest date that this supply is required by any project task associated with it through a **TaskSupplyLink** record. If this order is not required by any tasks, then 'undefined' is reported. **Note:** This field belongs to the ProjMgmt namespace.	Date	
ToleranceProfile Zone	A reference to the entry in the ToleranceProfileZone table that applies to this ScheduledReceipt record. It is used in defining the acceptable levels of change when comparing scheduled receipts against baseline historical supply series. The ToleranceProfile for this record is the value referenced from the PartSupplier field, and the ToleranceProfileZone is set to the entry with the lowest ZoneEndInterval value where `Part.PlanningCalendars.RunDate.FirstDate + ZoneEndInterval ToleranceProfile.ToleranceCalendar > ScheduledReceipt.EffDueDate`. **Referenced table**: ToleranceProfileZone	Reference	
Allocations	Set of Allocation records for components that are required when making this order, but which have yet to be removed from inventory.	Set	
CostInfo	Set of **ScheduledReceiptCost** records that contain cost values associated with the set of supplies needed to complete this order. Used in calculations that populate the **CostOfGoodsSold** field.	Set	
CRPOperation States	Set of **CRPOperationState** records used to identify the current operation(s) and the quantity of those work order that has been completed or run through that operation.	Set	

Table 6.297: Calculated ScheduledReceipt (Mfg) fields

Field name	Description	Data type	Key
Notes	A Set of ScheduledReceipt_Notes records. This field can used to enter notes about an scheduled receipt. Each time a note value is added to this field through a worksheet, a new record is created in the ScheduledReceipt_Notes table with a date and timestamp, user ID, note text, and a reference to the ScheduledReceipt record against which it was created.	Note	
TaskSupplyLinks	Set of TaskSupplyLink records that link this scheduled receipt to project tasks.	Set	

Segment table

The **Segment** table describes the segments associated with parts made in a production wheel. This table is an optional and only contains data if your company defines segmentation strategies to use in production planning.

This table was added in Service Update 1902.

Table 6.298: Segment(Solutions) fields

Field name	Description	Data type	Key
Description	A description of the segment.	String	
Recurrence	A reference to the input table that defines how often a part can be produced in a selected production wheel. Referenced table: ProductionRecurrence	Reference	
Site	The site associated with this segment.	Reference	Yes
SortKey	How segments are organized. This field only displays values for segments that have an assigned sort strategy. For example, the Glenday Sieve technique sorts segments by color (Green > Yellow > Blue > Red).	String	
Strategy	The sorting strategy applied to the segments. This field only displays values for segments that have an assigned sorting strategy.	String	
Value	A unique identifier for this segment record. Only one segment can be associated with a part.	String	Yes

Segment table – calculated and set fields

The following describes the calculated and set fields in the **Segment** table. For an introduction to this table, and descriptions of its input fields, see "Segment table" on page 589

Table 6.299: Segment(Solutions) fields

Field name	Description	Data type	Key
PartSolutions	Set of PartSolution records associated with this Segment.	Set	

SequenceFlow table

The SequenceFlow table links the flow of activities within a process instance, meaning it links an activity to its prerequisite and subsequent activities.

Table 6.300: SequenceFlow (ProcOrch) fields

Field name	Description	Data type	Key
Source	The source activity of the link.		
Target	Target activity of the link.		

SequenceFlow table –calculated and set fields

The following describes the calculated and set fields in the SequenceFlow table. For an introduction to this table, and descriptions of its input fields, see "SequenceFlow table" on page 590.

Table 6.301: SequenceFlow (ProcOrch) fields

Field name	Description	Data type	Key
IsRecursive	Indicates if a recursive relationship exists between the prerequisite and subsequent activities.	Boolean	

Shipment table

The **Shipment** table stores the details about individual shipments from a supplier to the manufacturer.

Individual scheduled receipts must be associated with a shipment. Initially, you can supply a single default record as the default shipment.

Table 6.302: Shipment (Mfg) fields

Field name	Description	Data type	Key
Airport	An airport where this shipment is transferred. Typically, this is a reference to a **LogisticsLocation** record where **Type** is set to "Airport." **Referenced table**: LogisticsLocation (Nullable) **Note:** This table was added in Version 2016.2, Service Update 9	Reference	
Carrier	The name of the carrier for this shipment. **Referenced table:** Carrier (this reference is nullable in new installations of RapidResponse 10.1 and later).	Reference	
Customs	A customs location that this shipment passes through. Typically, this is a reference to a **LogisticsLocation** record where **Type** is set to "Customs." **Referenced table**: LogisticsLocation (Nullable) **Note:** This table was added in Version 2016.2, Service Update 9	Reference	
DeliveryDateTime	Date and time this shipment is scheduled to arrive. **Default value**: Undefined	Date Time	
Id	The name for this shipment. The name is arbitrary, but must be unique in combination with Supplier. The Shipment ID is needed as the key value while allowing other fields to be editable. **Default value**: Unassigned	String	Yes
Port	A port where this shipment is transferred. Typically, this is a reference to a **LogisticsLocation** record where **Type** is set to "Port." **Referenced table**: LogisticsLocation (Nullable) **Note:** This table was added in Version 2016.2, Service Update 9	Reference	
ShipDateTime	Date and time this shipment is scheduled to be shipped or was shipped. **Default value**: Undefined	Date Time	
Supplier	The supplier that is providing the goods being shipped in this shipment. **Referenced table:** Supplier **Reference Syntax**: Supplier.Id, Supplier.Site	Reference	Yes
Waybill	The waybill number for this shipment. **Default value**: blank string	String	

Shipment table – calculated and set fields

The following describes the calculated and set fields in the Shipment table. For an introduction to this table, and descriptions of its input fields, see "Shipment table" on page 590.

Table 6.303: Calculated Shipment (Mfg) fields

Field name	Description	Data type	Key
Scheduled Receipts	Set of ScheduledReceipt records included in this shipment.	Set	

ShipSet table

The **ShipSet** table is used to identify ship sets, which are groups of independent demands from the same demand order that are required to ship together as a whole order. Values are automatically loaded into this table from **IndependentDemand** records during a data import or update.

Table 6.304: ShipSet (Mfg) fields

Field name	Description	Data type	Key
Description	A description of this ship set.	String	
Type	A reference to the ship set type. Used to control processing of the ship set when non-blocking allocations are used. **Referenced table:** ShipSetType (Nullable)	Reference	
Value	A unique identifier for this ship set.	String	Yes

ShipSet table – calculated and set fields

The following describes the calculated and set fields in the ShipSet table. For an introduction to this table, and descriptions of its input fields, see "ShipSet table" on page 592.

Table 6.305: Calculated ShipSet (Mfg) fields

Field name	Description	Data type	Key
Independent Demands	The set of independent demands that belong to this ship set.	Set	

Shop table

The **Shop** table contains information identifying unique shop floor locations used in a kanban material replenishment system. It is also used to set the date horizon for calculations that populate some fields in the **ShopKanban** table.

This table's **Site** field is optional, and a system or data administrator can choose whether it uniquely identifies records in the table, or is ignored in queries, and not shown in insert definitions, dialog boxes, or the Data Sources and Mapping window.

Table 6.306: Shop (Mfg) fields

Field name	Description	Data type	Key
Address	A unique identifier for a shop floor location.	String	Yes
Description	A description of the shop floor location.	String	
Site	The site where this shop is located. This field is optional. **Referenced table:** Site	Reference	Yes
KanbanHorizon	The number of days out from today that Kanban Manager considers when calculating the average daily demand for kanban parts at this shop address (past due demands are also included in this horizon).	Integer	

For more information about making the **Site** field optional, see "Modifying table and field properties" in the *RapidResponse Data Integration Guide*.

Shop table – calculated and set fields

The following describes the calculated and set fields in the Shop table. For an introduction to this table, and descriptions of its input fields, see "Shop table" on page 593.

Table 6.307: Calculated Shop (Mfg) fields

Field name	Description	Data type	Key
Allocations	The set of Allocation records associated with this shop floor location.	Set	
BOMs	The set of BillOfMaterial records associated with this shop floor location.	Set	
Kanbans	The set of ShopKanban records associated with this shop floor location.	Set	

ShopKanban table

The **ShopKanban** table is used to model parameters for a kanban material replenishment system within a factory. Each record in this table is uniquely identified by a part and shop floor location, and contains current and recommended details on bins at this ShopKanban. For example, it indicates the current number and size of bins for each ShopKanban, and also holds new calculated recommendations for these values.

This table supports the Kanban Manager workbook. It contains fields into which data should be imported if your company uses ShopKanbans, as well as fields that are populated by Kanban Manager calculations as discussed in . For more information, see "Kanban Manager calculations" on page 2239.

Table 6.308: ShopKanban (Mfg) fields

Field name	Description	Data type	Key
BinLocation	The exact storage location for this ShopKanban. **Default value**: blank string	String	
BinQty	The current approved quantity contained within each bin for this ShopKanban. **Default value**: 0	Integer	
Bins	Total number of bins currently approved for this ShopKanban. **Default value**: 0	Integer	
BinType	The type of bin used for this ShopKanban. **Default value**: blank string	String	
LastEvaluation Date	For a given scenario, the date on which Kanban Manager last evaluated, and possibly recommended changes to, the bin size and quantities for this ShopKanban. **Default value**: unassigned	Date	
MaximumBinQty	The maximum quantity of the part that can fit into the type of bin designated for this ShopKanban. This value establishes an upper limit for the bin quantity recommendation provided by Kanban Manager. If this value is < 0, then no upper limit is considered. **Default value**: 0	Integer	
Part	The name of a part which has been designated as a ShopKanban part. **Referenced table:** Part **Reference Syntax:** Part.Name, Part.Site	Reference	Yes

Table 6.308: ShopKanban (Mfg) fields

Field name	Description	Data type	Key
Replenishment Period	The frequency in which bin replenishment for this ShopKanban is desired. It is specified in work days, and decimals can be used to indicate partial work days. For example, a value of 2 indicates bins should be replenished every 2 days, and a value of .5 indicates bins should be replenished every half day. This value is used by Kanban Manager when calculating the recommended bin quantity. **Default value**: 0	Quantity	
Replenishment LeadTime	The number of work days it takes to replenish an empty bin of the part with a full one. This includes any transit times, and decimals can be used to indicated partial work days. This value is used by Kanban Manager when calculating the recommended number of bins. **Default value**: 0	Quantity	
SafetyFactor	A decimal factor used to increase the average daily demand value to account for normal variations in demand and delivery reliability. For example, specifying .25 indicates a 25% increase in average daily demand. **Default value**: 0	Quantity	
Shop	A shop floor location where consumption of the part occurs. **Referenced table:** Shop	Reference	Yes

ShopKanban table– calculated and set fields

The following describes the calculated and set fields in the ShopKanban table. For an introduction to this table, and descriptions of its input fields, see "ShopKanban table" on page 594. For information about the calculations used to populate these fields, see "Kanban Manager calculations" on page 2239.

Table 6.309: ShopKanban (Mfg) fields

Field name	Description	Data type	Key
AverageDaily Demand	The average daily demand calculated by Kanban Manager for this ShopKanban over the time horizon established by **Shop.KanbanHorizon**. This value includes any past due demands, and is used by Kanban Manager when recommending the bin quantity and number of bins. For information on how this field is calculated, see "Average daily demand" on page 2240. **Default value**: 0	Quantity	
Recommended BinQty	The recommended bin quantity for this ShopKanban as calculated by Kanban Manager. This value is calculated by multiplying AverageDailyDemand by the ReplenishmentPeriod, and is subject to both MaximumBinQty and PartSource.MultipleQty. For more information on how this field is calculated, see "Recommended bin quantity" on page 2241. **Default value**: 0	Integer	
Recommended Bins	The recommended number of bins for this ShopKanban as calculated by Kanban Manager. This value is calculated based on the current bin quantity. It does not consider any Kanban Manager recommendations for changes in bin quantity. For more information on how this field is calculated, see "Recommended number of bins" on page 2241. **Default value**: 0	Integer	

Site table

The **Site** table contains valid site codes. An entry should be provided for each site value in the enterprise data.

This table is referenced by many other tables. The Site field in these other tables is usually a key field, which keeps planning data from different sites separate. For example, there might be different constraints affecting production at different locations, or different quantities of a part on hand at different locations.

Types of sites

RapidResponse supports two types of sites: manufacturing/physical and inventory/logical.

Manufacturing/Physical

A manufacturing/physical site is an individual location within a company (or a company's subsidiary or a company's third-party manufacturing facilities) that segregates its supply and demand from other

locations, for example, a plant, a specific geographic location, and so on. Typically, manufacturing, assembly of products, or both occur at this type of site.

Data from manufacturing/physical sites is used to model supply and demand, and model the building of supply to support demand. The part data associated with manufacturing/physical sites includes a BOM structure.

Enterprise data sources are often used as a site identifiers.

Inventory/Logical

Inventory/logical sites are used to identify units, such as business units and inventory hubs. An inventory/logical site is often an inventory location, and it segregates its supply and demand from other locations. Examples include retail site, hub, VMI, and order consolidation.

These types of sites are primarily used to model a source of supply, demand, or both.

The part data associated with the inventory/logical site type does not involve transformation of one part into another (for example, processing, assembly, and so on) and should not include any BOM structures. RapidResponse analytics (including netting) must not be used in modeling exercises that explode BOM structures.

Table 6.310: Site (Core) fields

Field name	Description	Data type	Key
Address	The street address of the site. If this table is used to support maps, the address in this field determines the geocode that is used to mark the site's location on the map. To ensure that the correct geocode is used, follow the guidelines outlined in "Using address data to support maps" on page 1735. **Note:** This field was added in Version 2016.2, Service Update 9.	String	
ControlSet	The ControlSet record that data in this site is typically expected to use. **Referenced table:** ControlSet	Reference	
Currency	The default currency used for Money values at this site. **Referenced table**: Currency (Nullable)	Reference	
Description	Additional information about the site. **Default value**: blank string	String	

Table 6.310: Site (Core) fields

Field name	Description	Data type	Key
LicenseType	Indicates the type of site license. Valid values are: • **Logical**—This type of site is used to identify units, such as a specific business unit or a customer product line, within one physical site. In RapidResponse, this type of license is also referred to as Inventory/Logical. • **Physical**—This type of site is used to identify an individual location within a company that has separately defined enterprise data, such as a plant or a specific geographic location. In RapidResponse, this type of license is also referred to as Manufacturing/Physical. For more information, see "Types of sites" on page 596.	String (Enum)	
Region	The name of the region this site belongs to. For example, this might refer to a state or country. **Referenced table:** Region (Nullable)	Reference	
TimeZone	The name of the time zone associated with this site. **Referenced table:** TimeZone	Reference	
Type	The valid site types for reporting purposes only. Valid values are: • Distribution Center1 • Distribution Center2 • Distribution Center3 • Miscellaneous • ProductionFinishedGoods • ProductionSubAssembly • WarehouseFinishedGoods • WarehouseIncomingSupply **Default value**: ProductionFinishedGoods	String (Enum)	
Value	The key string used to reference a Site record (for example, from the Part table, or from the WorkCenter table if the **Capacity Planning - Constraints** application is enabled). **Default value**: blank string **Caution:** Avoid including leading or trailing spaces in Site names. In some cases, this can lead to the Site not being visible in the RapidResponse interface (for example, from a workbook's Site control).	String	

Site table – calculated and set fields

The following describes the calculated and set fields in the Site table. For an introduction to this table, and descriptions of its input fields, see "Site table" on page 596.

Table 6.311: Calculated Site (Core) fields

Field name	Description	Data type	Key
LastDataUpdate	The date and time of the last data update or import for this site. **Note:** This field is obsolete.	DateTime	
ABCCodes	The set of values in the ABCCode table associated with this site.	Set	
BonusSchedules	Set of BonusSchedule records associated with this site.	Set	
BuyerCodes	Set of BuyerCodes records associated with this site.	Set	
Constraints	Set of Constraint records associated with this site.	Set	
Customers	Set of Customer records associated with this site.	Set	
DeliveryRoutes	Set of DeliveryRoute records associated with this site.	Set	
DemandOrders	Set of DemandOrder records for this site.	Set	
Departments	Set of Department records at this site.	Set	
HistoricalDemand Orders	Set of HistoricalDemandOrder records associated with this site.	Set	
HistoricalShipments	Set of HistoricalShipment records associated with this site.	Set	
HistoricalSupply Orders	Set ofHistoricalSupplyOrder records associated with this site.	Set	
Parts	Set of Part records associated with this site.	Set	
PenaltySchedules	Set of PenaltySchedule records associated with this site.	Set	
PlannerCodes	Set of PlannerCode records associated with this site.	Set	
ProductionGroups	Set of ProductionGroup records associated with this site.	Set	
ProductionWheels	Set of ProductionWheel records associated with this site.	Set	
Projects	Set of Project records associated with this site.	Set	

Table 6.311: Calculated Site (Core) fields

Field name	Description	Data type	Key
Resources	Set of Resource records associated with this site.	Set	
Routings	Set of Routing records associated with this site.	Set	
SafetyLeadTime Profiles	Set of SafetyLeadTimeProfile records associated with this site.	Set	
Segments	Set of Segment records associated with this site.	Set	
Shops	Set of Shop records at this site.	Set	
SiteManagers	Set of SiteManager records associated with this site.	Set	
Sources	Set of Source records associated with this site.	Set	
SubstituteGroups	Set of SubstituteGroup records associated with this site.	Set	
Suppliers	Set of Supplier records associated with this site.	Set	
SupplyOrders	Set of SupplyOrder records for this site.	Set	
Warehouses	Set of Warehouse records at this site.	Set	
WorkCenter	Set of WorkCenter records associated with this site.	Set	

SiteManager table

This table is used to track information about management roles at different company sites.

Data in this table do not affect analytic functionality.

This table was added in Version 2016.2, Service Update 9 to support the Supply Chain Health dashboard, which is part of the S&OP Application. For more information about applications, see the *RapidResponse Applications Guide*.

Table 6.312: SiteManager (Mfg) fields

Field name	Description	Data type	Key
Description	A description of this site manager's responsibilities.	String	
Site	The site that this manager is responsible for. **Referenced table:** Site	Reference	Yes
Type	The type of site manager. Because a site might have more than one manager—for example, a Plant manager and a Logistics manager—this key field makes it possible to include records for different types of managers at the same site. **Referenced table:** SiteManagerType	Reference	Yes
Value	Identifier for this management position.	String	

SiteManagerType table

This table is used to define different site manager types. For example, the roles of Plant manager and Logistics manager at a site might be filled by different people.

Data in this table do not affect analytic functionality.

This table was added in Version 2016.2, Service Update 9 to support the Supply Chain Health dashboard, which is part of the S&OP Application. For more information about applications, see the *RapidResponse Applications Guide*.

Table 6.313: SiteManagerType (Mfg) fields.

Field name	Description	Data type	Key
Description	Description of the site manager type.	String	
Value	Identifier for the site manager type.	String	Yes

SiteManagerType table – calculated and set fields

The following describes the set field in the SiteManagerType table. For an introduction to this table, and descriptions of its input fields, see "SiteManagerType table" on page 601.

Table 6.314: SiteManagerType (Mfg) fields

Field name	Description	Data type	Key
SiteManagerTypes	The SiteManager records associated with this SiteManagerType.	Set	

SiteMetric table

The **SiteMetric** table identifies the combination for each site and metric definition generated for a specific as of date that are used in live lens and comparison scorecards.

This table was added in Version 2016.2, Service Update 19.

Table 6.315: SiteMetric (Solutions) fields

Field name	Description	Data type	Key
AsOf	A reference to the date on which the site and metric definitions are generated.	Reference	Yes
Metric	A reference to the metric associated with this combination of site and metric definition data. **Referenced table:** Metric	Reference	Yes
Site	A reference to the part the associated with this combination of site and metric definition data. **Referenced table:** Site	Reference	Yes

SiteMetric table – calculated and set fields

The following describes the calculated and set fields in the SiteMetric table. For an introduction to this table, and descriptions of its input fields, see "SiteMetric table" on page 602.

Table 6.316: SiteMetric (Solutions) fields

Field name	Description	Data type	Key
SiteMetricValues	The set of site calculations that belong to this combination of site and metric definition data. **Referenced table:** SiteMetricValues	Set	

SiteMetricValues table

The **SiteMetricValues** table stores the site calculations for metrics used in live lens and comparison scorecards.

This table was added in Version 2016.2, Service Update 19.

Table 6.317: SiteMetricValues (Solutions) fields

Field name	Description	Data type	Key
Date	The date associated with this calculation.	Date	Yes
SiteMetric	A reference to the site and metric definition combination associated with this calculation. **Referenced table:** SiteMetric	Reference	Yes
Quantity	The quantity for the metric. The value in this field is used if Metric.ValueType= 'Quantity'. For more information, see "Metric table" on page 399.	Quantity	
Value	The money value for the metric. The value in this field is used if Metric.ValueType= 'Money'. For more information, see "Metric table" on page 399.	Money	

Source table

The **Source** table stores information about deliveries, as well as information pertaining to contact people at suppliers. This table is referenced from the PartSource table.

Table 6.318: Source (Mfg) fields

Field name	Description	Data type	Key
Carrier	The name of the transportation carrier for this source. **Referenced table**: Carrier **Note:** This field was added in Version 2016.2, Service Update 5.	Reference	
ContactName	Full name for this source (often the contact person).	String	
DestinationSite	The site expected to consume from this source. **Referenced table:** Site	Reference	Yes
Email	The email address for the contact.	String	
EstimatedCost	An estimate of the shipping cost associated with using this source for an order. It can be used to express relative costs between sources. **Note:** This field was added in Version 2016.2, Service Update 9.	Money	

Table 6.318: Source (Mfg) fields

Field name	Description	Data type	Key
Id	Identifier for this source.	String	Yes
LeadTimeUnit	Calendar to use when calculating start date. **Referenced table:** Calendar	Reference	
Phone	The phone number for the contact.	String	
PreShipLT	The number of **Source.LeadTimeUnits** to allow between the supply-side stock date and the ship date for supplies using this source. This field gives time for the source to collect the inventory and prepare it for shipment. Values less than zero are treated as zero. **NOTE**: If this value is expected to change over time, the TimePhasedSourceLeadTime table can be used instead.	Quantity	
ShipCalendar	Calendar to use when determining Ship Date. **Referenced table:** Calendar	Reference	
Supplier	Identifies the supplier this record represents. **Referenced table:** Supplier **Reference Syntax:** Supplier.Id	Reference	Yes
TransitCalendar	A reference to the calendar in which the **TransitTime** value should be expressed. For example, if the trucks used to transport goods from the sourcing site to the destination site are not permitted on roads during weekends, this might be set to a standard Workday calendar. If this reference is left Null, then an Everyday calendar is assumed. **Referenced table:** Calendar (Nullable) **Note:** This field was added in Version 2016.2	Reference	
TransitTime	The amount of time required to ship supply from the sourcing site to the destination site. This field represents time between the **ShipDate** and **DockDate**, and is typically only applicable to transfer sources. This should be expressed in **TransitCalendar** intervals (or the Everyday calendar if the **TransitCalendar** reference is Null). **NOTE**: If this value is expected to change over time, the TimePhasedSourceLeadTime table can be used instead.	Quantity	

Table 6.318: Source (Mfg) fields

Field name	Description	Data type	Key
Transportation Mode	The transportation mode, including carrier and delivery route, for this source. **Referenced table**: TransportationMode (Nullable) **Note:** This field was added in Version 2016.2, Service Update 5.	Reference	

Source table – calculated and set fields

The following describes the calculated and set fields in the Source table. For an introduction to this table, and descriptions of its input fields, see "Source table" on page 603.

Table 6.319: Calculated Source (Mfg) fields

Field name	Description	Data type	Key
Collaborative Forecasts	Set of CollaborativeForecast records that reference this Source record. **Note:** This field is only applicable to RapidResponse legacy applications.	Set	
HistoricalSupply Actuals	Set of HistoricalSupplyActual records that reference this Source record.	Set	
PartSources	Set of PartSource records that reference this Source record.	Set	
TimePhasedLeadTimes	Set of TimePhasedSourceLeadTime records that reference this Source record.	Set	

SourceConstraint table

This table supports the Constraint Manager application, and defines constraint factors for part sources. Each record in this table defines the fixed and variable amounts of a constraint needed to produce supply from a given part source.

If constraint factors are not expected to change over time, then only one SourceConstraint record is required for a given constraint and part source combination. Otherwise, if constraint factors on a part source vary over time, then multiple time-phased SourceConstraint records can be defined.

Therefore, the combination of the Constraint, PartSource and EffectiveInDate fields must be unique for each record in this table. Otherwise, data integrity is violated and the record is not imported into this table.

Table 6.320: SourceConstraint (Mfg) fields

Field name	Description	Data Type	Key
CampaignFixed ConstraintFactor	If the part source is enabled for campaign planning (has **OrderPolicy.MaximumUsage** set to "CampaignPlanning"), this represents the major cleanup associated with the constraint (typically, equipment). It represents a fixed amount of constraint that gets consumed before each campaign can begin, and is time used to clean up or prepare the constraint to process supply of a particular part. Note that if the part source is not enabled for campaign planning, then the factor defined in this field is ignored. **Note:** This field supports the optional Campaign Planning capability.	Quantity	
Constraint	The constraint that this record references. Usually constraint will not be a constraint with Type=**Unconstrained** (RapidResponse calculations ignore such supplemental source constraints). A particular constraint record can only be used once in the set of SourceConstraints for the same part source. **Referenced table:** Constraint **Reference Syntax:** Constraint.Site, Constraint.Name	Reference	Yes
ConstraintFactor	The amount of the constraint required for each unit of supply from the referenced part source (in part source units). Thus, the variable amount of constraint required for a given supply is the product of the supply quantity and the value in this field.	Quantity	

Table 6.320: SourceConstraint (Mfg) fields

Field name	Description	Data Type	Key
EffectiveInDate	The date on which the fixed and variable constraint factors defined on this record become effective for the part source (inclusive). The factors are assumed to be effective until the next EffectiveInDate on a record for the same PartSource and Constraint combination. This field is intended to support situations where constraint factors vary over time. For example, an operating process might improve over time (requiring a factor decrease) or a machine might degrade over time (requiring a factor decrease). Similarly, if the constraint factors should be ignored over a period of time, then they can be set to zero (0). If constraint factors are never expected to change, then this field can be left at the default value. **Default value**: Past **Note:** This field was added in Version 2016.2, Service Update 3. **Note:** The earliest record whose effectivity overlaps with that of a given part source has its EffectiveInDate artificially extended to "Past" (this prevents an issue with setting the constraint factor to 0 but without a SourceConstraint to reference).	Date	Yes
FixedConstraint Factor	The fixed amount of the constraint required for each supply from the referenced part source (in part source units). Note that if the part source is enabled for campaign planning (has **OrderPolicy.MaximumUsage** set to "CampaignPlanning"), then this factor represents the minor clean-up between batches. It is a fixed amount of constraint consumed before each batch in a campaign (other than the first batch per campaign which has no minor clean up associated with it.	Quantity	
PartSource	The part source constrained by this constraint. **Referenced table**: PartSource **Reference Syntax:** PartSource.Part.Site, PartSource.Part.Name, PartSource.Source.Id, PartSource.Source.Supplier.Id, PartSource.BaseKey	Reference	Yes

SourceKanban table

The SourceKanban table is used to model parameters for a kanban material replenishment system from a given source. Each record in this table is associated with exactly one part source, and contains current and recommended details on bins at this SourceKanban. For example, it indicates the current number and size of bins for each SourceKanban, and also holds new calculated recommendations for these values.

This table supports the Kanban Manager workbook. It contains fields into which data should be imported if your company uses SourceKanbans, as well as fields that are populated by Kanban Manager calculations which are described in "SourceKanban table — calculated and set fields" on page 609. For information about the calculations used to populate these fields, see "Kanban Manager calculations" on page 2239.

Table 6.321: SourceKanban (Mfg) fields

Field name	Description	Data type	Key
BinLocation	The exact storage location for the SourceKanban. **Default value**: assigned	String	
BinQty	The current approved quantity contained within each bin for this SourceKanban. **Default value**: 0	Integer	
Bins	Total number of bin currently approved for this SourceKanban. **Default value**: 0	Integer	
BinType	The type of bin used for this SourceKanban. **Default value**: blank string	String	
KanbanHorizon	The number of days out from today that Kanban Manager considers when calculating the average daily demand for this SourceKanban. **Default value**: 0	Integer	
LastEvaluationDate	For a given scenario, the date on which Kanban Manager last evaluated, and possibly recommended changes to, the bin size quantities for this SourceKanban. **Default value**: unassigned	Date	
MaximumBinQty	The maximum quantity of the part that can fit into the type of bin designated for this SourceKanban. This value establishes an upper limit for the bin quantity recommendation provided by Kanban Manager. If this value is < 0, then no upper limit is considered. **Default value**: 0	Integer	
PartSource	The source of supply for the part designated as a SourceKanban part. **Referenced table**: PartSource **Reference Syntax**: PartSource.Part.Site, PartSource.Part.Name, PartSource.Source.Id, PartSource.Source.Supplier.Id, PartSource.BaseKey	Reference	Yes

Table 6.321: SourceKanban (Mfg) fields

Field name	Description	Data type	Key
Replenishment Period	The frequency in which bin responsibility for this SourceKanban is desired. It is specified in work days, and decimals can be used to indicate partial work days. For example, a value of 2 indicates bins should be replenished every 2 days, and a value of .5 indicates bins should be replenished every half day. This value is used by Kanban Manager when calculating the recommended bin quantity. **Default value**: 0	Quantity	
SafetyFactor	A decimal factor used to increase the average daily demand value to account for normal variations in demand and delivery reliability. For example, specifying .25 indicates a 25% increase in average daily demand. **Default value**: 0	Quantity	

SourceKanban table – calculated and set fields

The following describes the calculated and set fields in the SourceKanban table. For an introduction to this table, and descriptions of its input fields, see "SourceKanban table" on page 607. For information on the calculations used to populate this table, see "Kanban Manager calculations" on page 2239.

Table 6.322: SourceKanban (Mfg) fields

Field name	Description	Data type	Key
AverageDaily Demand	The average daily demand calculated by Kanban Manager for this SourceKanban over the time horizon established by KanbanHorizon. This value includes any past due demands, and is used by Kanban Manager when recommending the bin quantity and number of bins. For information on how this field is calculated, see "Average daily demand" on page 2240. **Default value**: 0	Quantity	
RecommendedBin Qty	The recommended bin quantity for this SourceKanban as calculated by Kanban Manager. This value is calculated by multiplying AverageDailyDemand by the ReplenishmentPeriod, and is subject to both the MaximumBinQty and PartSource.MultipleQty. For more information on how this field is calculated, see "Recommended bin quantity" on page 2241. **Default value**: 0	Integer	

Table 6.322: SourceKanban (Mfg) fields

Field name	Description	Data type	Key
Recommended Bins	The recommended number of bins for this SourceKanban as calculated by Kanban Manager. This value is calculated based on the current bin quantity. It does not consider any Kanban Manager recommendations for changes in bin quantity. However, this information is available in the Kanban Manager workbook. For more information on how this field is calculated, see "Recommended number of bins" on page 2241. **Default value**: 0	Integer	

StorageType table

The **Storage** table is used to define storage types for storage locations in the Distribution Requirements Planning application. For example, a storage type value could be Freezer or Cage. The settings in this table are referenced by the **PartSolution** table.

This table was added in the Version 2016.2, Service Update 5, to support the Distribution Requirements Planning application.

Table 6.323: StorageType (Solutions) fields

Field name	Description	Data type	Key
Value	A string identifier for this storage type. This field is referenced by **PartSolution.StorageType**.	String	Yes
Description	A description of this storage type. This field can used to enter a description about the storage type.	String	

SubProcess table

This table holds records that define hierarchical parent-child relationships between process instance activities. Parent activities are usually sub-processes and child activities are activities.

Table 6.324: SubProcess (ProcOrch) fields

Field name	Description	Data type	Key
Child	The child activity in the sub-process and child relationship. **Referenced table**: Activity (ProcOrch)	Reference	
Parent	The parent activity in the sub-process and child relationship. **Referenced table:** Activity (ProcOrch)	Reference	

SubProcess table—calculated and set fields

The following describes the calculated and set fields in the SubProcess table. For an introduction to this table, and descriptions of its input fields, see "SubProcess table" on page 610.

Table 6.325: SubProcess (ProcOrch) fields

Field name	Description	Data type	Key
IsRecursive	Indicates if a recursive relationship exists between sub-processes.	Boolean	

SubstituteGroup table

The **SubstituteGroup** table is used to define groups of substitutable components within an assembly. For example, a substitute group might define a group of components that can be substituted for one another within an assembly, or a group of components that can collectively be substituted for another group of components within an assembly.

All records in the **BillOfMaterial** table that define a group of substitutable components within a given assembly must reference the same **SubstituteGroup** record. Additionally, to ensure expected results from bom-level substitution, it is recommended that multiple assemblies not reuse the same group(s) to define their substitutable components. Thus there should typically be at least as many **SubstituteGroup** records as there are unique groups of substitutable components across all assemblies.

The **SubstituteGroup** table can also be used to define substitutable allocations under scheduled receipts. All records in the **Allocation** table that represent a group of substitutable allocations under a given scheduled receipt should reference the same SubstituteGroup record.

Note: For more information about using substitute groups, see "BOM level part substitution" on page 1565.

Table 6.326: SubstituteGroup (Mfg) fields

Field name	Description	Data type	Key
Description	A description of this group of substitutable components.	String	
Site	The site associated with this group of substitutable components. Together with the Value field, this uniquely identifies each record in the table. **Referenced table**: Site	Reference	

Table 6.326: SubstituteGroup (Mfg) fields

Field name	Description	Data type	Key
Type	A value that defines the processing rules associated with this group of substitutable components. For example, can multiple components within the group be used within a single order for the group's assembly. **Referenced table:** SubstituteGroupType	Reference	
Value	An identifier for this group of substitute components. This value is referenced by each BillOfMaterial record that defines a group of substitutable components within a given assembly. It also referenced by each Allocation record that defines a group of substitutable components under a given scheduled receipt.	String	Yes

SubstituteGroup table – calculated and set fields

The following describes the calculated and set fields in the SubstituteGroup table. For an introduction to this table, and descriptions of its input fields, see "SubstituteGroup table" on page 611.

Table 6.327: Calculated SubstituteGroup (Mfg) fields

Field name	Description	Data type	Key
Allocations	Set of Allocation records which reference this SubstituteGroup.	Set	
BillOfMaterials	Set of BillOfMaterial records which reference this SubstituteGroup.	Set	

Supplier table

The **Supplier** table is a repository for supplier information. A Supplier may be a vendor for a purchase order, a work center for work orders, or a plant identifier for inter-plant orders.

This table's **Site** field is optional, and a system or data administrator can choose whether it uniquely identifies records in the table, or is ignored in queries, and not shown in insert definitions, dialog boxes, or the Data Sources and Mapping window.

Table 6.328: Supplier (Mfg) fields

Field name	Description	Data type	Key
Address	The street address of this supplier. If this table is used to support maps, the address in this field determines the geocode that is used to mark the supplier's location on the map. To ensure that the correct geocode is used, follow the guidelines outlined in "Using address data to support maps" on page 1735. **Note:** This field was added in Version 2016.2, Service Update 9.	String	
ContactName	Name of this supplier's contact person. **Note:** This field was added in Version 2016.2, Service Update 9.	String	
DefaultShipment	The name of the shipment to use as the default for this supplier. The field is a string so that data can be loaded. **Default value**: blank string	String	
Email	The email address of the contact person listed in the **ContactName** field. **Note:** This field was added in Version 2016.2, Service Update 9.	String	
Id	A value that identifies the supplier. **Default value**: unknown	String	Yes
Name	The name of the supplier. **Default value**: blank string	String	
Phone	The phone number of the contact person listed in the **ContactName** field. **Note:** This field was added in Version 2016.2, Service Update 9.	String	
Region	The name of the region associated with this supplier. **Referenced table:** Region (nullable)	Reference	
Site	The site associated with this supplier. This field is optional. **Referenced table:** Site	Reference	Yes
SupplierGroup	The group this supplier is in. **Referenced table**: SupplierGroup (this reference is nullable in new installations of RapidResponse 10.1 and later).	Reference	

For more information about making the **Site** field optional, see “Modifying table and field properties” in the *RapidResponse Data Integration Guide*.

Supplier table – calculated and set fields

The following describes the calculated and set fields in the Supplier table. For an introduction to this table, and descriptions of its input fields, see "Supplier table" on page 612.

Table 6.329: Calculated Supplier (Mfg) fields

Field name	Description	Data type	Key
Contacts	Set of Source records referencing this supplier.	Set	
Orders	Set of SupplyOrder header records for existing orders from this supplier.	Set	
PartSuppliers	Set of PartSupplier records referencing this supplier.	Set	
Shipments	Set of Shipment records for this supplier.	Set	

SupplierGroup table

The SupplierGroup table defines groups that different suppliers can be placed under. If your company’s host system uses more than one name to refer to the same supplier, they can be placed in the same group, and the group name used to refer to the supplier.

Table 6.330: SupplierGroup (Mfg) fields

Field name	Description	Data type	Key
Id	The supplier group name	String	Yes
Description	A description of this group. This can be the supplier’s company name or a general classification for several different companies.	String	

SupplierGroup table – calculated and set fields

The following describes the calculated and set fields in the SupplierGroup table. For an introduction to this table, and descriptions of its input fields, see "SupplierGroup table" on page 614.

Table 6.331: Calculated SupplierGroup (Mfg) fields

Field name	Description	Data type	Key
Suppliers	The Supplier records in this group.	Set	

SupplierMetric table

The **SupplierMetric** table identifies the combination for each supplier and metric definition generated for a specific as of date that are used in live lens and comparison scorecards.

This table was added in Version 2016.2, Service Update 22.

Table 6.332: SupplierMetric (Solutions) fields

Field name	Description	Data type	Key
AsOf	A reference to the date on which the supplier and metric definitions are generated. **Referenced table:** MetricAsOf	Reference	Yes
Metric	A reference to the metric associated with this combination of supplier and metric definition data. **Referenced table:** Metric	Reference	Yes
Supplier	A reference to the part the associated with this combination of supplier and metric definition data. **Referenced table:** Supplier	Reference	Yes

SupplierMetric table – calculated and set fields

The following describes the calculated and set fields in the SupplierMetric table. For an introduction to this table, and descriptions of its input fields, see "SupplierMetric table" on page 615.

Table 6.333: SupplierMetric (Solutions) fields

Field name	Description	Data type	Key
SupplierMetricValues	The set of site calculations that belong to this combination of supplier and metric definition data. **Referenced table:** SupplierMetricValues	Set	

SupplierMetricValues table

The **SupplierMetricValues** table stores the supplier calculations for metrics used in live lens and comparison scorecards.

This table was added in Version 2016.2, Service Update 22.

Table 6.334: SupplierMetricValues (Solutions) fields

Field name	Description	Data type	Key
Date	The date associated with this calculation.	Date	Yes
SupplierMetric	A reference to the supplier and metric definition combination associated with this calculation. **Referenced table:** SiteMetric	Reference	Yes
Quantity	The quantity for the metric. The value in this field is used if Metric.ValueType= 'Quantity'. For more information, see "Metric table" on page 399.	Quantity	
Value	The money value for the metric. The value in this field is used if Metric.ValueType= 'Money'. For more information, see "Metric table" on page 399.	Money	

SupplyAllocation table

The SupplyAllocation table stores manual allocations of supply to demand entered or imported into RapidResponse. For example, a demand manager may create these manual supply allocations to reserve limited supply amongst multiple requesting demand sites. To model these manual allocations, corresponding orders are created in the PlannedOrder table and identified as “Manual” in the Origin field. As necessary, RapidResponse will also automatically generate planned orders at the PTFDate to satisfy any supply shortages introduced by the manual allocations.

Table 6.335: SupplyAllocation (Mfg) fields

Field name	Description	Data type	Key
DestinationPart	The part whose demand this supply allocation was created to satisfy. **Referenced table**: Part	Reference	
Id	An identifier used to uniquely identify this supply allocation record. **Default value**: SupplyAllocation	String	Yes

Table 6.335: SupplyAllocation (Mfg) fields

Field name	Description	Data type	Key
Model	The model that applies to this supply allocation. It is set to None if either of the following conditions apply: • Model-Unit Effectivity is not enabled • MUEPoolNettingType.ModelRule for the part is set to Ignore. **Referenced table**: Model	Reference	
OrderPriority	The priority associated with this supply allocation. **Referenced table**: OrderPriority	Reference	
Pool	The pool associated with this supply allocation. **Referenced table**: Pool	Reference	
Quantity	The number of units that this supply allocation is for. This value is expressed in inventory units of measure at the supplying site. However, the amount received at the destination site is adjusted for yield on the transfer part source (for example, to reflect any loss during transportation).	Quantity	
StartUnit	The start unit number that applies to this supply allocation. It is set to None if either of the following conditions apply: • Model-Unit Effectivity is not enabled. • MUEPoolNettingType.UnitRule is set to Ignore.	Integer	
SupplyDate	The date the supply is removed from the source part's site.	Date	
PartSource	The part source used for this supply allocation. **Referenced table**: PartSource **NOTE:** Manual supply allocations are not compatible with constrained part sources and can result in unexpected analytic results if used together. However, constraints at the sourcing site are respected as appropriate.	Reference	
Type	A value that determines the processing rules associated with this supply allocation. For example, whether the supply allocation is processed by RapidResponse analytics. **Referenced table**: SupplyAllocationType	Reference	

SupplyAllocation table – calculated and set fields

The following describes the calculated and set fields in the SupplyAllocation table. For an introduction to this table, and descriptions of its input fields, see "SupplyAllocation table" on page 616.

Table 6.336: SupplyAllocation (Mfg) fields

Field name	Description	Data type	Key
DestinationDate	The date this supply allocation is due at the destination site, based on the part source's lead time.	Date	
EffQuantity	The effective quantity, in supplier units of measure, of this supply allocation. If the **Type.ProcessingRule** is set to 'Ignore', this value is zero (0).	Quantity	
PartSupplier	A reference to the entry in the PartSupplier table, if any, that has the same part and supplier as this ScheduledReceipt record. **Referenced table**: PartSupplier	Reference	
ToleranceProfile Zone	A reference to the entry in the ToleranceProfileZone table that applies to this SupplyAllocation record. It is used in defining the acceptable levels of change when comparing supply allocations against baseline historical supply series. The ToleranceProfile for this record is the value referenced from the PartSupplier field, and the ToleranceProfileZone is set to the entry with the lowest ZoneEndInterval value where `Part.PlanningCalendars.RunDate.FirstDate + ZoneEndInterval ToleranceProfile.ToleranceCalendar > SupplyAllocation.DestinationDate`. **Referenced table**: ToleranceProfileZone	Reference	
Notes	A set of descriptive notes added to this supply allocation record. This field can be used to enter notes about an supply allocation record. Each time a note value is added to this field through a worksheet, a new record is created in the SupplyAllocation_Notes table with a date and timestamp, user ID, note text, and a reference to the SupplyAllocation record against which it was created.	Note	

SupplyOrder table

The **SupplyOrder** table is a repository for SupplyOrder information. Often supply orders are written up for multiple parts on a single order form. The header information is the common information about the whole order. Individual line items are entered in the **ScheduledReceipt** table. These line items reference the **SupplyOrder**. This information comes from work order (shop order), and purchase order files in most MRP systems.

Table 6.337: SupplyOrder (Mfg) fields

Field name	Description	Data type	Key
CampaignIndex	If the supply order represents a production campaign, this field identifies that campaign and the **Line** item on each scheduled receipt belonging to the order can be used to indicate the batch number. Otherwise, this field should be left blank. All scheduled receipts within a campaign-enabled supply order are assumed to belong to the same campaign and should be for the same quantity (batch size). Each of the receipts in the order should also reference the same **PartSource** record which should have an **OrderPolicy.MaximumUsage** value of "CampaignPlanning". This enables campaign functionality such as contiguous constraint consumption and the use of major and minor cleanup times when running the order through a constraint. Note however that because scheduled receipts are provided as input, the batch size, campaign minimum, and campaign maximum defined on the part source, which are enforced on generated planned orders, can potentially be overridden on scheduled receipts (either unintentionally, or as part of a simulation exercise to test different batch settings). **Note:** This field supports the optional Campaign Planning. For more information, see "Campaign planning" on page 1707.	String	
Currency	For an order that is undergoing a supplier collaboration process, the currency the order's money values use. This value is not a reference to the Currency table, and is used for information only. This field is taken from the IDOC message. This field is in the **SupCollab** namespace. This field maps to the CURCY field in the E1EDK01 segment of the IDOC message.	String	

Table 6.337: SupplyOrder (Mfg) fields

Field name	Description	Data type	Key
DateQualifier	For an order received from the Real-time Integration Service, identifies how the date and time fields are used in the IDOC message that generated the order. This field is taken from the IDOC message and can contain the following values: • **003**—The date and time fields represent the order's requested delivery date. • **005**—The date and time fields represent a value-added service date. • **006**—The date and time fields represent the order's cancellation date. • **007**—The date and time fields represent the order's price determination date. • **014**—The date and time fields represent the validity start date for an agreement. • **022**—The date and time fields represent a date for services. • **023**—The date and time fields represent the valid start date for picking up a delivery order. • **024**—The date and time fields represent the valid end date for picking up a delivery order. This field is in the **SupCollab** namespace. This field maps to the IDDAT field of the E1EDK03 segment of the IDOC message.	String	
DocQualifier	For an order received from the Real-time Integration Service, identifies the type of order the IDOC message generates. This field is taken from the IDOC message and can contain the following values: • **001**—A customer purchase order. • **004**—A vendor quotation. • **007**—A collective. • **050**—A delivery order. • **066**—An external order. This field is in the **SupCollab** namespace. This field maps to the QUALF field of the E1EDK02 segment of the IDOC message.	String	

Table 6.337: SupplyOrder (Mfg) fields

Field name	Description	Data type	Key
Flag	For an order that is undergoing a supplier collaboration process, indicates whether an order acknowledgement is required. This field is taken form the IDOC message and can contain the following values: • **Y**—An acknowledgment is required. • **N**—An acknowledgment is not required. This field is in the **SupCollab** namespace. This field maps to the KZABS field of the E1EDK01 segment of the IDOC message.	Boolean	
Id	A value that identifies an order number for a ScheduledReceipt record. **Default value**: blank string	String	Yes
IDOCDateTime	For an order received from the Real-time Integration Service, the date and time the order's IDOC message was generated. This field is taken from the IDOC message. This field is in the **SupCollab** namespace. The Date component of this field maps to the DATUM field of the E1EDK02 segment of the IDOC message. The Time component of this field maps to the UZEIT field of the E1EDK02 segment of the IDOC message.	DateTime	
Organization	For an order received from the Real-time Integration Service, identifies the organization that generated the IDOC message for the order. This field is taken from the IDOC message. This field is in the **SupCollab** namespace. This field maps to the ORGID field of the E1EDK14 segment of the IDOC message.	String	

Table 6.337: SupplyOrder (Mfg) fields

Field name	Description	Data type	Key
OrgQualifier	For an order received from the Real-time Integration Service, identifies the division or organization that generates the order. This field is taken from the IDOC message and can contain the following values: • **006**—The order was generated by a division of your company. • **007**—The order was generated by a member of your distribution channel. • **008**—The order was generated by a sales organization. • **009**—The order was generated by a purchasing group. • **010**—The order was generated by a sales group. • **011**—The order was generated by a company. • **012**—The order was generated as a specific sales order type. • **013**—The order was generated as a specific purchase order type. • **014**—The order was generated by a purchasing organization • **016**—The order was generated by a sales office. This field is in the **SupCollab** namespace. This field maps to the QUALF field of the E1EDK14 segment of the IDOC message.	String	
PartnerFunc	For an order received from the Real-time Integration Service, the function provided by the trading partner. This field is taken from the IDOC message and can contain the following values: • **AG**—The partner is the organization the order is sold to. • **WE**—The partner is the organization the order is shipped to. • **RE**—The partner is the organization the order is billed to. • **RG**—The partner is paying for the order. This field is in the **SupCollab** namespace. This field maps to the PARVW field of the E1EDKA1 segment of the IDOC message.	String	
PaymentTerms	The term of payment for an order received from the Real-time Integration Service. This field is taken from the IDOC message. This field is in the **SupCollab** namespace. This field maps to the QUALF field of the E1EDK18 segment of the IDOC message.	String	

Table 6.337: SupplyOrder (Mfg) fields

Field name	Description	Data type	Key
Pool	The pool to which this order belongs. This field supports inventory pooling and is ignored unless **Part.MUEPoolNettingType.PoolRule** is set to 'Net'or 'NetOptional'. For all other **PoolRule** settings, or for implementations not using the Pool capabilities, all supplies belong to the part's common pool (as defined by the **Part.PlanningCalendars.CommonPool** reference). If any line items under the order have their **InputPool** reference populated, then that referenced pool is used instead. For example, this might be done when pools do not easily correspond to items associated with a supply order or when there is a need to inject pool information at the component level based on an assembly's scheduled supply. **Referenced table:** Pool **Reference Syntax:** Pool.Value	Reference	
PurchaseGroup	The name of a person or group of people operating within a segment of the purchasing organization. This field maps to the ORGID field of the E1EDK14 segment of the IDOC message. This field is in the **Solutions** namespace.	String	
Purchase Organization	The name of a company's purchasing organization. This field maps to the ORGID field of the E1EDK14 segment of the IDOC message. This field is in the **Solutions** namespace.	String	
Site	The site this supply order relates to. **Referenced table**: Site	Reference	Yes
Supplier	The supplier for the order. This field references the Supplier table. For information about this table, see "Supplier table" on page 612. **Referenced table:** Supplier **Reference Syntax:** Supplier.Id	Reference	
TextId	Identifies a note about an order that has been received from an enterprise data source through the Real-time Integration Service. This field is taken from the IDOC message. This field is in the **SupCollab** namespace. This field maps to the TDID field of the E1EDKT1 segment of the IDOC message.	String	

Table 6.337: SupplyOrder (Mfg) fields

Field name	Description	Data type	Key
TextLine	For an order undergoing a supplier collaboration process, the notes provided by the buyer and supplier about the order. This field is taken from the IDOC message. Typically, these notes describe the quantity or delivery date changes made to the order, and are the primary channel of communication between the buyer and supplier. This field is in the **SupCollab** namespace. This field maps to the TDLINE field of the E1EDKT1.E1EDKT2 segment of the IDOC message.	Note	
Type	A value that determines the processing policies of ScheduledReceipts. This field references the SupplyType table. For information about this table, see "SupplyType table" on page 919. **Referenced table:** SupplyType	Reference	Yes

SupplyOrder table – calculated and set fields

The following describes the calculated and set fields in the SupplyOrder table. For an introduction to this table, and descriptions of its input fields, see "SupplyOrder table" on page 618.

Table 6.338: Calculated SupplyOrder (Mfg) fields

Field name	Description	Data type	Key
Lines	Set of line items (ScheduledReceipt records) for this order.	Set	

Task table

The **Task** table defines all individual work items or tasks that together form the basis of a project. Besides a reference to the applicable project, each record in this table contains task-level input details such as task name, the rule used for calculating duration, and any constraints on task start or finish dates. As necessary, a given task can also be assigned dependencies on other tasks, material availabilities, and resources that perform work towards task completion. Additionally, this table reports calculated project-level details such as start and finish dates, task duration, and any material, resource, or penalty costs applied to the project.

This table's records can be edited using the **Project Plan** workbook included with RapidResponse. When using this workbook, or any Task-based worksheet that has been automatically configured for project management, certain calculated fields become editable. For example, the calculated start date (**CalcStartDate**) and finish date (**CalcFinishDate**) can be edited, as can the calculated list of a task's predecessors (**PredecessorList**). For more information about worksheets automatically configured for project management, see the *RapidResponse Resource Authoring Guide*.

Table 6.339: Task (ProjMgmt) fields

Field name	Description	Data type	Key
ActualCost	Used to specify any actual costs incurred while completing this task that aren't reflected in the defined resource or material costs. Useful for comparison against the **Cost** field to see how actual miscellaneous costs track against the planned miscellaneous costs.	Money	
ActualDuration	The actual number of days of work completed since the task was started. Used when calculating the **CalcDuration** and **CalcPercentComplete** fields. If populating this field, a value should typically be provided for the **RemainingDuration** field as well.	Quantity	
ActualFinishDate	The date work actually completed on the task (if applicable). For automatically scheduled tasks, if this field is populated then the date is also reported in **CalcFinishDate**. Also used in calculating the task state (for example, an undefined value here indicates the task has not yet finished), as well as by certain task calculations in projects where **ProjectType.PlanningRule** is set to "DateDriven".	Date	
ActualStartDate	The date work actually began on the task (if applicable). For automatically scheduled tasks, if this field is populated then the date is also reported in **CalcStartDate**. Also used in calculating the task state (for example, an undefined value here indicates the task has not yet started), as well as by certain task calculations in projects where **ProjectType.PlanningRule** is set to "DateDriven".	Date	
ActualWork	The actual amount of work that has already been completed on this task. Used when calculating the **CalcActualWork** and **CalcPercentComplete** fields.	Quantity	
ApplyRate Adjustment	Indicates if the resource rate adjustment specified in the **RateAdjustment** field will be applied to resources assigned to this task. Valid values are: • **N**—adjustment can be applied. • **Y**—adjustment is ignored.	Boolean	
BonusDate	The date on or before which bonuses can potentially be applied to this task. Bonuses are calculated based on the referenced **BonusSchedule** and **TaskType** values, and can be applied to projects that finish on or before this date (bonuses can accumulate between **CalcFinishDate** and **BonusDate**).	Date	

Table 6.339: Task (ProjMgmt) fields

Field name	Description	Data type	Key
BonusSchedule	The name of the bonuses schedule used for calculating project bonuses. Together with the rules defined on the project type, this determines how bonuses are calculated at the project level. **Referenced table:** BonusSchedule (Nullable)	Reference	
ConstraintDate	A date-based constraint to apply to scheduling of the task. The interpretation of this date is determined by the **ConstraintType** setting (all types other than "None", "AsLateAsPossible", and "AsSoonAsPossible" rely on this value). For example, this might define a date the task must finish on or a date the task cannot start before. Note that applying constraints to tasks limits the degree to which the project can be scheduled in RapidResponse, but might be useful when there are external factors influencing the task start or finish date.	Date	

Table 6.339: Task (ProjMgmt) fields

Field name	Description	Data type	Key
ConstraintType	Contains rules used to constrain task start or finish dates. Typically, these rules are applied to the date specified in the **ConstraintDate** field to either fix the task start or finish date, or provide boundaries for a possible start or finish date. Note that certain constraint types always honor the constraint date and might lead to conflicts with other scheduling parameters such as predecessor tasks or material order availability. The details of such conflicts are then reported in the **Conflict** table. Alternatively, other constraint types can be chosen that enforce the constraint date only so long as it does not lead to a conflict with other scheduling parameters. Valid values are: • **AsLateAsPossible**—task is scheduled to finish as late as it can (for tasks in project's with a ScheduleRule of "FromStart", this reverses the normal task scheduling logic). • **AsSoonAsPossible**—task is scheduled to start as soon as it can (for tasks in project's with a ScheduleRule of "FromStart", this reverses the normal task scheduling logic). • **FinishOn**—task is scheduled to finish on the constraint date unless this would conflict with another scheduling parameter. • **FinishOnOrAfter**—task is scheduled to finish on or after the constraint date unless this would conflict with another scheduling parameter. • **FinishOnOrBefore**—task is scheduled to finish on or after the constraint date unless this would conflict with another scheduling parameter. • **MustFinishOn**—task is always scheduled to finish on the constraint date. • **MustFinishOnOrAfter**—task is always scheduled to finish on or after the constraint date. • **MustFinishOnOrBefore**—task is always scheduled to finish on or before the constraint date. • **MustStartOn**—task is always scheduled to start on the constraint date. • **MustStartOnOrAfter**—task is always scheduled to start on or after the constraint date. • **MustStartOnOrBefore**—task is always scheduled to start on or before the constraint date specified. • **None**—task is scheduled without any constraint applied. If the task belongs to a project that has a **ProjectType.ScheduledRule** of "FromStart", then it is scheduled as early as possible. Otherwise, if the task belongs to a project that has a	String (Enum)	

Table 6.339: Task (ProjMgmt) fields

Field name	Description	Data type	Key
	ProjectType.ScheduledRule of "FromFinish", then it is scheduled as late as possible. • **StartOn**—task is scheduled to start on the constraint date unless this would conflict with another scheduling parameter. • **StartOnOrAfter**—task is scheduled to start on or after the constraint date unless this would conflict with another scheduling parameter. • **StartOnOrBefore**—task is scheduled to start on or before the constraint date unless this would conflict with another scheduling parameter. **Default value**: None **Note:** For more information about this field's usage, see "Task constraints" on page 2172 and "Constraint conflicts" on page 2174.		
Cost	Used to provide any planned costs associated with completing this task that aren't reflected in the defined resource or material costs. Subsequently used when calculating **Project.TaskCost**.	Money	
Description	Descriptive details about this task.	String	
Duration	An input value for the task duration used in determining the actual or calculated duration as reported in the **CalcDuration** field. The usage of this field is dependent on the setting in the **DurationType** field.	Quantity	

Table 6.339: Task (ProjMgmt) fields

Field name	Description	Data type	Key
DurationType	Contains rules used to set how the task duration is calculated and reported in the **CalcDuration** field. Valid values are: • **FixedDuration**—calculated task duration is typically fixed and set to the input value provided in the **Duration** field. Note that in run date-driven projects, if actual start date and either actual or expected finish dates are provided, the duration is calculated based on those dates. • **FixedUnits**—calculated task duration is determined by the resources assigned to the task (in units). The input **Duration** value is divided by the cumulative resource units assigned to the task through **ResourceAssignment.Units**. Otherwise, if no resources are assigned to the task, then the value provided in the **Duration** field is used instead. • **FixedWorkAndRate**—calculated task duration is determined by the provided work and rate values. For tasks without resources assigned, this is calculated by dividing the value in the **Work** field by the value in **Rate** field. For tasks with resources assigned, the work and rate values can be overridden by providing **ActualWork**, **RemainingWork**, and **Rate** values on the **ResourceAssignment** table. Otherwise, if no valid work and rate values are provided (for example, if Rate <= 0), then the value provided in the **Duration** field is used instead. **Default value:** FixedUnits For more information about how this field is used, see "Task durations" on page 2176.	String (Enum)	
ExpectedFinishDate	The date work on the task is expected to be completed. This value is used in calculating the finish date for **FixedDuration** tasks that are in progress in projects where the **ProjectType.PlanningRule** is set to "DateDriven".	Date	
FinishDate	If **SchedulingRule** is set to "Manual", this field can be used to provide an input finish date on which the task must finish. Otherwise, if **SchedulingRule** is set to "Automatic", then RapidResponse automatically calculates a realistic finish date based on other input parameters and this field is ignored (can be left undefined). **Note:** If there is a requirement to fix the finish date of automatically scheduled tasks on or before a given date, then a "FinishNoEarlierThan" task constraint can be used.	Date	
Id	A unique string identifier for this task.	String	Yes

Table 6.339: Task (ProjMgmt) fields

Field name	Description	Data type	Key
Links	A string field used to hold URLs which can then be used to hyperlink to externally stored documents relevant to the task or project. For example, a link to related engineering specifications might be required.	String	
Milestone	Specifies if the task is a milestone. Typically, these are used to mark important points on the project schedule. For example, a milestone might indicate the point at which revenue can be recognized. Valid values are: • **N**—a normal task. • **Y**—a milestone task. Note that milestone tasks in projects where **ProjectType.AllowNonZeroMilestones** is set to "N" (the default setting) do not contain work to complete, do not generate resource loads, and always have a **CalcDuration** of 0. Otherwise, if **AllowNonZeroMilestones** is set to "Y", then a milestone task can represent actual work and have a positive calculated duration.	Boolean	
Name	A name to associate with this task. This value should make the task easy to recognize or identify by those working on the project.	String	
Notes	Descriptive notes appended to this task (for example, an explanation of why a task is expected to be late). Each time a note value is added to this field through a worksheet, a new record is created in the **Task_Notes** table with a datetime stamp, user ID, note text, and a reference to the Task record against which it was created.	Note	
OriginalStartDate	An optional field not used by analytic calculations, but which can be used to store a copy of the value returned by the CalcStartDate field for baseline comparison against future calculated results.	Date	
OriginalFinishDate	An optional field not used by analytic calculations, but which can be used to store a copy of the value returned by the CalcFinishDate field for baseline comparison against future calculated results.	Date	
PenaltyDate	The date from which penalties can potentially accumulate to this task. Penalty costs are calculated based on the referenced **PenaltySchedule** and **TaskType** values, and can be applied between this date and CalcFinishDate. For more information about how this field is used, see "Penalties" on page 2191.	Date	

Table 6.339: Task (ProjMgmt) fields

Field name	Description	Data type	Key
PenaltySchedule	The name of the penalty schedule used for calculating task penalties. Together with the rules defined on the task type, this determines how penalties are calculated at the task level. **Referenced table:** PenaltySchedule (Nullable)	Reference	
PointsCurve	A reference to the set of points that constitute the efficiency curve applied to resources assigned to this task when **Type.EfficiencyCurveRule** is set to "PointsCurve". **Referenced table:** PointsCurve (Nullable)	Reference	
Project	A reference to the project this task belongs to. **Referenced table:** Project	Reference	Yes
Ramp	Value used to construct a linear increasing efficiency curve. The resulting efficiency curve is then applied to resources assigned to this task when **Type.EfficiencyCurveRule** is set to "Ramp". Note that the value specified in this field determines the number of distinct points on the resulting curve, with the points spread evenly between 0 and 1. For example, if a value of 5 is specified, resources on this task have an efficiency of .2 on the first date, .4 on the second date, .6 on the third date, .8 on the fourth date, and 1 (full efficiency) on the fifth and all subsequent dates. Using this curve, a task that is otherwise expected to have a duration of 4 days, would have a duration of 6 days instead.	Integer	
Rate	If **Task**.**DurationType** is "FixedWorkAndRate", then this value can be used to determine the rate at which work is completed on the task (and hence impacts the calculated task duration). Otherwise, this field is ignored. For example, assume a task with Work of "5"and Rate of "1.25". The calculated task duration would then be 4; that is, (5 /1.25). **Note:** If the task has resources assigned to it, then this value can be overridden by providing values in the **ResourceAssignment.Rate** field.	Quantity	

Table 6.339: Task (ProjMgmt) fields

Field name	Description	Data type	Key
RateAdjustment	An optional percentage adjustment to be applied to the standard and overtime rates charged for any resources assigned to this task. This value is considered only if **ApplyRateAdjustment** is set to "Y". If the adjustment represents a premium charged on resources rates, a positive value should be specified. If the adjustment represents a discount applied to resource rates, a negative value should be specified. For example, .15 indicates a 15 percent premium while -.2 indicates a 20 percent discount. Note that this adjustment overrides any adjustments specified at the project level, however if there is an adjustment specified at a more granular task level, then that value is used instead of this one. For example, adjustments can also be specified for only certain resources applied to the task. For more information, see "Resource rate adjustments" on page 2189. However, if there is a more resource specific adjustment specified on the task, then that value is used instead of this one.	Quantity	
RemainingDuration	The amount of days remaining until the task is completed. Used when calculating the **CalcDuration** field. If populating this field, a value should typically be provided for the **ActualDuration** field as well.	Quantity	
Revenue	Used to provide a revenue amount associated with this task. Subsequently used when calculating **Project.TaskRevenue**.	Money	
SchedulingRule	A rule used to determine how the task's calculated start and finish dates (**CalcStartDate** and **CalcFinishDate**) are determined. Valid values are: • **Automatic**—task start and finish dates are automatically calculated by RapidResponse based on project start/finish dates, predecessor task dates, material order availability, constraints, and other parameters. • **Manual**—task start and finish dates are set to the input values provided in the **StartDate** and **FinishDate** fields. This option might typically be used in the early stages of project when all task details and timings are not known. **Default value**: Automatic **Note:** For more information about how tasks are scheduled, see "Task scheduling" on page 2167.	String (Enum)	

Table 6.339: Task (ProjMgmt) fields

Field name	Description	Data type	Key
SortKey	String value used to sort tasks in the project hierarchy. Typically, represented as a period-delimited list of integers (for example, 2.1.1).	String	
StartDate	If **SchedulingRule** is set to "Manual", this field can be used to provide an input start date on which the task must start. Otherwise, if **SchedulingRule** is set to "Automatic", then RapidResponse automatically calculates a realistic start date based on other input parameters and this field is ignored (can be left undefined).	Date	
Type	A value associated with processing rules that control certain calculations at the project level, such as how task duration and penalties are determined. **Referenced table:** TaskType	Reference	
Work	If **Task**.**DurationType** is "FixedWorkAndRate", then this value is used to determine the amount of work to be done on the task (and hence impacts the calculated task duration). Otherwise, this field is not used in calculating task duration. For example, assume a task with Work of "6"and Rate of "1.". The calculated task duration would then be 6; that is, (6 / 1). **Note:** If the task has resources assigned to it, then this value can be overridden by providing values in the **ActualWork** and **RemainingWork** fields on the **ResourceAssignment** table.	Quantity	

Task table – calculated and set fields

The following describes the calculated and set fields in the Task table. All calculated fields that are directly editable in any worksheets automatically configured for project management, such as in the Project Plan workbook, are also noted. For an introduction to this table, and descriptions of its input fields, see "Task table" on page 624.

Table 6.340: Calculated Task (ProjMgmt) fields

Field name	Description	Data type	Key
ActualMaterial Cost	Total actual material cost summed across all demand and/or supply order dependencies associated with this task as follows: • For any portion of a material part requirement assigned to a supply order, the assigned quantity is multiplied by the **CostofGoodsSold** on the **ScheduledReceipt** record, and then divided by the **EffQuantity** on the **ScheduledReceipt** record. • For any portion of a material part requirement assigned to a demand order, the assigned quantity is multiplied by the value in **IndependentDemand.CostOfGoodsSold** and then divided by the value in **IndependentDemand.EffectiveDemand**.	Money	
Bonus	Bonuses earned at the task level. Task bonuses can only be earned on dates between **CalcFinishDate** and **BonusDate**, where the **BonusSchedule** field references a valid bonus schedule, and the referenced **ProjectType.BonusRule** value is other than "None". For more information about how this field is calculated, see "Bonuses" on page 2196. **Note:** All task-level bonuses are added to any project-level bonuses and together reported in the **Project.CumulativeBonus** field.	Money	
CalcActualDuration	The calculated number of days of work completed since the task was started. If the task belongs to a project where **Type.PlanningRule** is set to "Standard", this field always reports the value found in the **ActualDuration** field. Otherwise, if the task belongs to a project where **Type.PlanningRule** is set to "DateDriven", then this field is calculated based on the task's progress state as follows: • when **CalcState** returns "NotStarted", this field is set to zero (0). • when **CalcState** returns "InProgress", this field is calculated as the difference between the project's current working date and the task's calculated start date as follows: *Project.RunDate - CalcStartDate* • when **CalcState** returns "Completed', this field is set to the value in **CalcDuration**.	Quantity	

Table 6.340: Calculated Task (ProjMgmt) fields

Field name	Description	Data type	Key
CalcActualWork	The calculated amount of work that has already been completed on this task. If the task has any resources assigned to it, this is the sum of all applicable **ResourceAssignment.ActualWork** values. Otherwise, if there are no resources assigned, this is set to the value in **ActualWork**.	Quantity	
CalcDuration	The amount of time this task is calculated to take. If the **SchedulingRule** field is set to "Automatic", then the duration is calculated as follows: • For normal tasks, this field is calculated based on the rule selected in the **DurationType** field as discussed in "Task durations" on page 2176. • For summary tasks, this value is calculated as the difference between the earliest calculated start date and latest calculated finish date on any sub-task. • For milestone tasks, this is always set to 0 if **ProjectType.AllowsNonZeroMilestones** is set to "N" (and calculated like a normal task otherwise). If the **SchedulingRule** field is set to "Manual", then the duration is calculated as follows: • For normal and summary tasks, if both the **StartDate** and **FinishDate** fields are defined, this is calculated as the difference between those two dates. Otherwise, set to the value in the input **Duration** field. • For milestone tasks, this is always set to 0 if **ProjectType.AllowsNonZeroMilestones** is set to "N" (and calculated like a normal task otherwise). **Note:** If using worksheets automatically configured for project management, such as in the Project Plan workbook included with RapidResponse, this field is directly editable.	Quantity	
CalcFinishDate	The calculated finish date for this task. If **ProjectType.ScheduledRule** is "FromStart", this is set to **EarliestFinishDate**. Otherwise, if **ProjectType.ScheduleRule** is "FromFinish", this is set to **LatestFinishDate**. **Note:** If using worksheets automatically configured for project management, such as in the Project Plan workbook included with RapidResponse, this field is directly editable	Date	

Table 6.340: Calculated Task (ProjMgmt) fields

Field name	Description	Data type	Key
CalcPercent Complete	Percentage of the task that is determined to be complete. This field holds values between 0 and 1 (with 1 meaning the task is 100% complete). For normal work tasks where **CalcDuration** > 0, this is calculated based on the number of days that have elapsed since work on the task started and the calculated task duration (*ActualDuration / CalcDuration*) under any of the following conditions: • **DurationType** is set to "FixedUnits". • **DurationType** is set to "FixedWorkAndRate". • **DurationType** is set to "FixedDuration" and **Project.Type.PercentCompleteRule** is set to "CalcDuration". Otherwise, calculated as whichever is greater of zero (0) or the amount of the original input duration that has not yet been completed (*Duration-CalcRemainingDuration/Duration*) under the following condition: • **DurationType** is set to "FixedDuration" and **Project.Type.PercentCompleteRule** is set to "OriginalDuration". For all milestone tasks belonging to projects where **ProjectType.AllowNonZeroMilestones** is set to "N", as well as well as any normal work tasks where **CalcDuration** = 0, calculated based on the following conditions: • If the task has predecessors, then 1 if every predecessor has **CalcPercentComplete** of "1", or 0 otherwise. • If the task does not have predecessors, then 1 if A**ctualStartDate** and **ActualFinishDate** are both defined, or 0 otherwise. For summary tasks, this returns a weighted average of the values in **CalcPercentComplete** from all of its subtasks. **Note:** If using worksheets automatically configured for project management, such as in the Project Plan workbook included with RapidResponse, this field is directly editable	Quantity	
CalcPercent Received	For tasks with any material part requirements, this indicates the percentage of the required quantity that has already been received (based on the **Quantity** and **CalcPercentReceived** values on all **TaskPartLink** records associated with this task).	Quantity	
CalcPercentWork Complete	Percentage of work on this task that has already been completed (based on the **CalcActualWork** and **CalcWork** values).	Quantity	

Table 6.340: Calculated Task (ProjMgmt) fields

Field name	Description	Data type	Key
CalcRemaining Duration	Amount of time remaining until this task is complete. Calculated as the difference between the number of days the task was calculated to take (CalcDuration) and the number of days that have already been worked on the task (CalcActualDuration)	Quantity	
CalcStartDate	The calculated start date for this task. If **ProjectType.ScheduledRule** is "FromStart", this is set to **EarliestStartDate**. Otherwise, if **ProjectType.ScheduleRule** is "FromFinish", this is set to **LatestStartDate**. For more information about calculated task start dates are determined, see "Task scheduling" on page 2167. **Note:** If using worksheets automatically configured for project management, such as in the Project Plan workbook included with RapidResponse, this field is directly editable.	Date	
CalcState	The calculated state of progress for this task based on actual start and finish dates. Valid values are: • **Completed**—For normal work tasks, this indicates that both the **ActualStartDate** and the **ActualFinishDate** are defined. For milestone tasks, this indicates that either the **ActualStartDate** or the **ActualFinishDate** are defined. For summary tasks, this indicates that all child tasks report a value of "Completed" in this field. • **InProgress**—For normal work tasks, this indicates that the **ActualStartDate** is defined but the **ActualFinishDate** is undefined.For summary tasks, this indicates that at least one child task reports a value of "InProgress" in this field. • **NotStarted**—For normal work tasks, this indicates that the **ActualStartDate** is undefined. For milestone tasks, this indicates that both the **ActualStartDate** and the **ActualFinishDate** are undefined. For summary tasks, this indicates that all child tasks report a value of "NotStarted" in this field.	String (Enum)	
CalcWork	The calculated amount of work to be completed on this task. If the task has any resources assigned to it, this is the sum of all applicable **ResourceAssignment.Work** values. Otherwise, if there are no resources assigned, this is set to the value in **Work**.	Quantity	

Table 6.340: Calculated Task (ProjMgmt) fields

Field name	Description	Data type	Key
Conflict	Indicates if the task has any scheduling conflicts that prevent the project plan from honoring all task parameters and limitations. Scheduling conflicts typically arise when a task constraint or material order link causes the task dates to move in the opposite direction from which the project is being scheduled. For example, when scheduling tasks from the project start date. a FinishNoLaterThan constraint might cause a conflict if its ConstraintDate pushes the task's start/finish dates earlier than they otherwise would be in respect of other scheduling parameters such as predecessor relationships. Valid values are: • **None**—The task does not have any conflicts. • **Primary**—The task has a conflict in the direction the project is currently scheduled. For example, if the task belongs to a project where **ProjectType.ScheduleRule** is set to "FromStart", this value indicates the task has a conflict as scheduled from the project start date and should be investigated. • **Secondary**—The task has a conflict in the opposite direction from which it is currently scheduled. For example, if the task belongs to a project where **ProjectType.ScheduledRule** is set to "FromStart", this value indicates the task would have a conflict if it were to be scheduled from the project finish date. **Note:** Details of each task conflict are reported in the **Conflict** table as described on page "Conflict table" on page 963.	String (Enum)	
Critical	Indicates if this task is on the critical path for its project. Tasks on the critical path are those which impact the project finish date (that is, tasks for which a delay would delay the project finish date). Valid values are: • **N**—task is not on critical path. • **Y**—task is on critical path.	Boolean	
CumulativeActual Cost	The sum of the **ActualCost** value on the current task and the **ActualCost** values found on all of its subtasks. This might be useful for reporting the miscellaneous costs associated with a summary task.	Money	
CumulativeActual MaterialCost	The sum of the **ActualMaterialCost** value on the current task and the **ActualMaterialCost** values found on all of its subtasks. This might be useful for reporting actual material costs associated with a summary task.	Money	

Table 6.340: Calculated Task (ProjMgmt) fields

Field name	Description	Data type	Key
CumulativeBonus	The sum of the **Bonus** value on the current task and the **Bonus** values found on all of its subtasks. This might be useful for reporting total bonuses associated with summary tasks.	Money	
CumulativeCost	The sum of the **Cost** value on the current task together with the **Cost** values found on all of its subtasks. This might be useful to reporting total costs associated with summary tasks.	Money	
CumulativeMaterial Cost	The sum of the **MaterialCost** value on the current task and the **MaterialCost** values found on all of its subtasks. This might be useful for reporting planned material costs associated with a summary task.	Money	
CumulativeMaterial Revenue	The sum of the **MaterialRevenue** value on the current task and the **MaterialRevenue** values found on all of its subtasks. This might be useful for reporting revenue associated with summary tasks.	Money	
CumulativePenalty Cost	The sum of the **PenaltyCost** value on the current task and the **PenaltyCost** values found on all of its subtasks. This might be useful for reporting total penalty costs associated with summary tasks.	Money	
CumulativeRevenue	The sum of the **Revenue** value on the current task together with the **Revenue** values found on all of its subtasks. This might be useful to reporting total revenue costs associated with summary tasks.	Money	
DaysLate	Indicates the number of days late the task is currently expected to be. Calculated as the difference between ActualDuration and the expected value of ActualDuration. A negative value in this field indicates a task that is ahead of schedule.	Quantity	

Table 6.340: Calculated Task (ProjMgmt) fields

Field name	Description	Data type	Key
EarliestFinishDate	The earliest date this task can finish. The calculation of this date depends on the setting in the **SchedulingRule** field as follows: • If **SchedulingRule** is set to "Automatic", then this date is calculated based on factors such as the input project start date, project run date, predecessor/successor relationships, order dependencies, resource availability, constraints, and so on. • If **SchedulingRule** is set to "Manual" and the **FinishDate** field is populated, then the value in **FinishDate** is used. Otherwise, if **FinishDate** is not populated, this is calculated by adding the value in **CalcDuration** to **StartDate.** **Note:** If **ProjectType.ScheduleRule** is set to "FromStart", this also becomes the task finish date as reported in **CalcFinishDate**.	Date	
EarliestStartDate	The earliest date this task can start. The calculation of this date field depends on the setting in the **SchedulingRule** field as follows: • If **SchedulingRule** is set to "Automatic", then this date is calculated based on factors such as the input project start date, project run date, predecessor/successor relationships, order dependencies, resource availability, constraints, and so on. • If **SchedulingRule** is set to "Manual" and the **StartDate** field is populated, then the value in **StartDate** is used. Otherwise, if **StartDate** is not populated, this is calculated by subtracting the value in **CalcDuration** from **FinishDate.** **Note:** If **ProjectType.ScheduleRule** is set to "FromStart", this also becomes the task start date as reported in **CalcStartDate**.	Date	
EffectiveCalendar	The calendar used when calculating start and finish dates for this task. If the task belongs to a task type that has a calendar value defined, then that value (**Task.Type.Calendar**) is used. Otherwise, the calendar defined at the project level (**Project.Type.Calendar**) is used.	Reference	
FreeSlack	The amount of time, in working days, the task can be delayed without delaying a successor task. If the task has no successors, this reports the same value as **TotalSlack**.	Quantity	

Table 6.340: Calculated Task (ProjMgmt) fields

Field name	Description	Data type	Key
Index	An index number that can be used to sort tasks across the entire project. Starts at 1 for the first top-level task in the project and increments by 1 for each additional task.	Quantity	
IsSummary	Indicates if the task is a summary task. Summary tasks roll up and summarize data from the sub-tasks (children) below them. Valid values are: For any portion of a material requirement assigned to a demand order, the assigned quantity is multiplied by the value in **IndependentDemand.CostOfGoodsSold** and then divided by the value in **IndependentDemand.EffectiveDemand**. • **N**—not a summary task. • **Y**—summary task.	Boolean	
LatestFinishDate	The latest date this task can finish. The calculation of this date field depends on the setting in the **SchedulingRule** field as follows: • If **SchedulingRule** is set to "Automatic", then this date is calculated based on factors such as the input project finish date, project run date, predecessor relationships, order dependencies, resource availability, constraints, and so on. • If **SchedulingRule** is set to "Manual" and the **FinishDate** field is populated, then the value in **FinishDate** is used. Otherwise, if **FinishDate** is not populated, this is calculated by adding the value in **CalcDuration** to **StartDate.** **Note:** If **ProjectType.ScheduleRule** is "FromFinish", this become the task finish date as reported in **CalcFinishDate**.	Date	
LatestStartDate	The latest date this task can start. The calculation of this date field depends on the setting in the **SchedulingRule** field as follows: • If **SchedulingRule** is set to "Automatic", then this date is calculated based on factors such as the input project finish date, project run date, predecessor/successor relationships, order dependencies, resource availability, constraints, and so on. • If **SchedulingRule** is set to "Manual" and the **StartDate** field is populated, then the value in **StartDate** is used. Otherwise, if **StartDate** is not populated, this is calculated by subtracting the value in **CalcDuration** from **FinishDate.** **Note:** If **ProjectType.ScheduleRule** is "FromFinish", this becomes the task start date as reported in **CalcStartDate**.	Date	

Table 6.340: Calculated Task (ProjMgmt) fields

Field name	Description	Data type	Key
MaterialCost	Total planned material cost summed across all material part requirements for the task. For each material part link defined, the quantity required is multiplied by the value in **Part.StdUnitCos**t.	Money	
MaterialRevenue	Revenue from all demand orders associated with this task. For each demand order, the quantity assigned to the task is multiplied by the value in **IndependentDemand.EffectiveUnitPrice**.	Money	
OutlineLevel	A number used to indicate the level of the task in the project structure. For example, top-level tasks have a value of "o", the next level of tasks down have values of "1", and so on.	Quantity	
OutlineNumber	A string value used to indicate the task's numerical position in the project's overall task hierarchy. For example, the first top-level task has a value of 1, and tasks underneath it have values such as 1.1., 1.2, and so on.	String	
Parent	A reference to the summary task, if any, this task belongs to. Otherwise, Null. **Referenced table:** Task	Reference	
PenaltyCost	Penalty costs incurred at the task level. Penalty costs can only be incurred on task dates between **PenaltyDate** and **CalcFinishDate**, where the **PenaltySchedule** field references a valid penalty schedule, and the referenced **TaskType.PenaltyRule** value is other than "None". For more information about how this field is calculated, see "Penalties" on page 2191. **Note:** Any task-level penalties are added to their project's penalties and together reported in the **Project.CumulativePenaltyCost** field.	Money	

Table 6.340: Calculated Task (ProjMgmt) fields

Field name	Description	Data type	Key
PredecessorList	A comma-delimited list of all predecessor's for this task (that is, those tasks that must come before this one) as defined in the **Predecessor** table. Predecessors tasks are referred to by **Index** value, and values in this field might also contain string details such as "SF" and "+5" to indicate the type of predecessor rule used along with any applicable offset value. For example, a value of "3FS+2" indicates the current task can start 2 days after the task with Index value of 3 finishes. **Note:** If using worksheets automatically configured for project management, such as in the Project Plan workbook included with RapidResponse, this field is directly editable and values entered here are added or updated in the **Predecessor** table.	String	
ResourceActual FixedCost	Actual fixed costs incurred during project execution when assigning resources to this task. Rolled up from associated values specified in the **ResourceCostActual.FixedCost** field.	Money	
ResourceActual OvertimeCost	Actual overtime costs incurred during project execution from assigned resources working on this task in excess of their maximum hours per day. Rolled up from associated values reported in the **ResourceCostActual.OvertimeCost** field.	Money	
ResourceActual StandardCost	Actual standard costs incurred during project execution from assigned resources working on this task up to their maximum hours per day. Rolled up from associated values reported in the **ResourceCostActual.StandardCost** field.	Money	
ResourceFixedCost	Reports the sum of all fixed (one-time) costs incurred from the assignment of resources to this task. If this is a summary task, the sum of fixed resource costs from all its subtasks is reported.	Money	
ResourceOvertime Cost	Reports the sum of all overtime hourly costs incurred by resources while assigned to this task. If this is a summary task, the sum of overtime resource costs from all its subtasks is reported.	Money	
ResourceStandard Cost	Reports the sum of all standard hourly working costs incurred by resources while assigned to this task. If this is a summary task, the sum of standard resource costs from all its subtasks is reported.	Money	

Table 6.340: Calculated Task (ProjMgmt) fields

Field name	Description	Data type	Key
SiblingIndex	An index number that can be used for sorting sibling tasks (that is, tasks with the same Parent value). Starts at 1 for each grouping of sibling tasks.	Quantity	
SuccessorList	A comma-delimited list of all successors's for the this task (that is, those tasks that must come after this one) as defined in the Predecessor table. Values in this field might also contain string details such as "FS" and "-2" to indicate the type of predecessor rule used along with any applicable offset. **Note:** If using worksheets automatically configured for project management, such as in the Project Plan workbook included with RapidResponse, this field is directly editable and values entered here are added or updated in the **Predecessor** table.	String	
TargetPercent Complete	Expected value of **CalcPercentComplete** if the project is on schedule. This calculation is based on the date returned by the **TaskType.RunDate** calendar.	Quantity	
TargetPercent WorkComplete	For fixed work and rate tasks, the expected percentage of work complete done on the task assuming the project is on schedule. This calculation is based on the date returned by the **TaskType.RunDate** calendar.	Quantity	
TargetWork Complete	For fixed work and rate tasks, the expected amount of work complete done on the task assuming that the project is on schedule. For tasks that do not have **DurationType** set to "FixedWorkAndRate", this always returns 0. This calculation is based on the date returned by the **TaskType.RunDate** calendar.	Quantity	

Table 6.340: Calculated Task (ProjMgmt) fields

Field name	Description	Data type	Key
TotalSlack	The amount of time, in working days, the task can be delayed without delaying the overall project finish date. By default, this field is calculated as: *min (LatestStartDate - EarliestStartDate, LatestFinishDate - EarliestFinishDate)* However, a project level control setting, **ProjectType.TotalSlackRule**, allows for this calculation to instead always use the difference the latest and earliest start date, or always use the difference between the latest and earliest finish date (regardless of which is less). Additionally, this field will always return a value of 0 (zero) in either of the following cases: • The task has an "AsLateAsPossible" constraint and belongs to a project scheduled from start. • The task has an "AsSoonAsPossible" constraint and belongs to a project scheduled from finish with **Type.ASAPBackwardTotalSlackRule** set to "Zero".	Quantity	
Assignments	Set of ResourceAssignment records that reference this Task value.	Set	
BaselineTaskLinks	Set of BaselineTaskLink records that reference this Task value.	Set	
Children	Set of WBS records that reference this Task value as a parent task.	Set	
DemandLinks	Set of TaskDemandLink records that reference this Task value.	Set	
Parents	Set of WBS records that reference this Task value as a child task.	Set	
PartLinks	Set of TaskPartLink records that reference this Task value.	Set	
Predecessors	Set of Predecessor records that reference this Task value as their successor.	Set	
Successors	Set of Predecessor records that reference this Task value as their predecessor.	Set	
SupplyLinks	Set of TaskSupplyLink records that reference this Task value.	Set	

TaskDemandLink table

The **TaskDemandLink** table associates project tasks with specific demand orders for parts that are required to complete those tasks. The availability of the demands (as defined by records in the **IndependentDemand** table) can then be used to constrain a task's start or finish date, as well as being used in calculating material costs for a task.

Note that in order to create a valid link between a task and a demand, a record must also be defined in the **TaskPartLink** table to link the task to the associated part, and that **TaskPartLink** record must have a **Type** value of "Demand".

If using Task-based worksheets automatically configured for project management, such as in the **Project Plan** workbook included with RapidResponse, values can be added to this table through the **Supply Chain** tab of the **Task Information** dialog box.

Table 6.341: TaskDemandLink (ProjMgmt) fields

Field name	Description	Data type	Key
ApplyConstraint	Indicates if the demand available date can potentially constrain the task start date or finish date. Valid values are: • **N**—available date of the linked demand does not impact the task start or finish date. • **Y**—available date of the linked demand impacts the task start date (if **Rule** = "StartDate") or task finish date (if **Rule** = "FinishDate"). **Default value:** Y	Boolean	
AssignedQuantity	The amount of the demand that has been assigned to this task.	Quantity	
Description	A description of this task and demand relationship.	String	
Independent Demand	A reference to a specific demand required to complete this task. **Referenced table:** IndependentDemand	Reference	Yes
Offset	The number of days to add to the demand's available date when determining the tasks' start date (if Rule = 'StartDate') or the task's finish date (if Rule = 'FinishDate'). This field is ignored if Rule = 'None' or ApplyConstraint = 'N'.. This field accepts positive, negative, and fractional values. For example, assuming a Rule of 'StartDate', an Offset of '2' means that the task cannot start earlier than two days after the demand's available date. Similarly, an Offset of '-1' means that the task cannot start earlier than the day before the demand's available date.	Quantity	

Table 6.341: TaskDemandLink (ProjMgmt) fields

Field name	Description	Data type	Key
PartLink	A reference to the task and part relationship that associates the task with the part it requires. **Referenced table:** TaskPartLink	Reference	
ReceivedQuantity	The amount of the demand that has already been received for this task.	Quantity	
Rule	Indicates how the availability of this demand constrains the task completion. Valid values are: • **FinishDate**—the task cannot finish any earlier than the demand's available date plus any applicable offset. Note that if **ApplyConstraint** is set to "N", then the task's finish date is not impacted by the constraint. • **None**—the task is not constrained by the demand available date. • **StartDate**—the task cannot start any earlier than the demand's available date plus any applicable offset. Note that if **ApplyConstraint** is set to "N", then the task's start date is not impacted by the constraint. **Default value:** None For more information about how this field is used, see "Supply and demand order links" on page 2171.	String (Enum)	
Task	A reference to the task that has a demand dependency. **Referenced table:** Task	Reference	Yes

TaskDemandLink table – calculated and set fields

The following describes the calculated and set fields in the TaskDemandLink table. For an introduction to this table, and descriptions of its input fields, see "TaskDemandLink table" on page 646.

Table 6.342: Calculated TaskDemandLink (ProjMgmt) fields

Field name	Description	Data type	Key
CalcPercent Received	The percentage of this demand's assigned quantity that has already been received by the task.	Quantity	
Critical	Indicates if the demand's availability determines when the task can be completed. Valid values are • N • Y	Boolean	

Table 6.342: Calculated TaskDemandLink (ProjMgmt) fields

Field name	Description	Data type	Key
MaterialCost	The cost associated with the quantity of parts assigned to this task from the referenced demand. Based on the sum of all values reported for this record in the **TaskDemandLinkCost** table.	Money	

TaskHyperlink table

The **TaskHyperlink** table is used to store links to internet locations containing more information about a particular project task. For example, links might be added to a page containing diagrams or specifications required for a particular task.

Records in this table are typically added using the **Add Links** dialog box available in the standard **Project Plan** workbook included with RapidResponse. Hyperlinks associated with a given task are then available from a popup menu in the **Links** column of the **Project Plan** worksheet.

Table 6.343: TaskHyperlink (ProjMgmt) fields

Field name	Description	Data type	Key
Description	A short description that displays beside the link label in the Links column popup menu.	String	
Index	A numerical index value used to sort hyperlinks in the Links popup menu (lower values display at the top of a given popup).	Integer	
Label	The clickable text that displays for this link in the Links popup menu (shows instead of the URL).	Label	
URL	The URL this hyperlink should point to. The value provided must begin with a proper formatted protocol (http:)	URL	
Task	A reference to the task this hyperlink pertains to. **Referenced table:** Task	Reference	Yes

TaskPartLink table

The **TaskPartLink** table associates project tasks with any manufactured parts required to complete the task. Once the link between a task and part has been defined, the task can subsequently be set up to have dependencies on specific demands or supplies for the part. These can impact task start and finish dates, and are also used in calculating material costs for a task.

If using Task-based worksheets automatically configured for project management, such as in the **Project Plan** workbook included with RapidResponse, values can be added to this table through the **Supply Chain** tab of the **Task Information** dialog box.

Table 6.344: TaskPartLink (ProjMgmt) fields

Field name	Description	Data type	Key
Description	A description of this task and part relationship.	String	
Part	A reference to a part required to complete the task. **Referenced table:** Part	Reference	Yes
Quantity	The amount of the part that is required to complete this task.	Quantity	
Received Quantity	The amount of the part that has already been received for this task. For tasks with supply or demand links defined, the **ReceivedQuantity** field on the **TaskSupplyLink** or **TaskDemandLink** table is used instead.	Quantity	
Task	A reference to the task that has a part dependency. **Referenced table:** Task	Reference	Yes
Type	Indicates which of demand orders for the part or supply orders for the part can be associated with this task. Valid values are: • **Demand**—this task, and hence its material costs as well as start or finish dates, can be tied to the availabilities of specific demands for the part. References made to the task through the **TaskDemandLink** table are valid and are used to associate the task with records in the **IndependentDemand** table. Any references to the task set up through the **TaskSupplyLink** table are ignored. • **Supply**—this task, and hence its material costs as well as start or finish dates, can be tied to the availabilities of specific supplies for the part. References made to the task through the **TaskSupplyLink** table are valid and are used to associate the task with records in the **ScheduledReceipt** table. Any references to the task set up through the **TaskDemandLink** table are ignored. **Default value:** Demand	String (Enum)	

TaskPartLink table – calculated and set fields

The following describes the calculated and set fields in the TaskPartLink table. For an introduction to this table, and descriptions of its input fields, see "TaskPartLink table" on page 648.

Table 6.345: Calculated TaskPartLink (ProjMgmt) fields

Field name	Description	Data type	Key
CalcPercent Received	The percentage of the part quantity that is required to complete the task and has already been received. For tasks with supply or demand links set up, the sum of the ReceivedQuantity field across all valid supply or demand links is used in calculating this value. Otherwise, for tasks with no supply or demand links, the ReceivedQuantity field in this table is used.	Quantity	
MaterialCost	Planned material cost for this part requirement on the task. Based on the sum of all values reported for this record in the **TaskPartLinkCost** table.	Money	
Unassigned Quantity	The quantity of the part that is required to complete the task, and has not yet been assigned from any valid supply or demand links.	Quantity	
DemandLinks	Set of TaskDemandLink records that reference this TaskPartLink value.	Set	
SupplyLinks	Set of TaskSupplyLink records that reference this TaskPartLink value.	Set	

TaskSupplyLink table

The **TaskSupplyLink** table associates project tasks with specific supply orders for parts that are required to complete those tasks. The availability of the supplies (as defined by records in the **ScheduledReceipt** table) can then be used to constrain a task's start or finish date, and is also used in calculating material costs for a task.

Note that in order to create a valid link between a task and a supply, a record must also be defined in the **TaskPartLink** table to link the task to the associated part, and that TaskPartLink record must have a **Type** value of "Supply".

If using Task-based worksheets automatically configured for project management, such as in the **Project Plan** workbook included with RapidResponse, values can be added to this table through the **Supply Chain** tab of the **Task Information** dialog box.

Table 6.346: TaskSupplyLink (ProjMgmt) fields

Field name	Description	Data type	Key
ApplyConstraint	Indicates if the supply available date can potentially constrain the task start date or finish date. Valid values are: • **N**—available date of the linked supply does not impact the task start or finish date. • **Y**—available date of the linked supply impacts the task start date (if **Rule** = "StartDate") or task finish date (if **Rule** = "FinishDate"). **Default value:** Y	Boolean	
AssignedQuantity	The amount of the supply that has been assigned to this task.	Quantity	
Description	A description of this task and supply relationship.	String	
Offset	The number of days to add to the supply's available date when determining the task start date (if Rule = 'StartDate') or the task finish date (if Rule = 'FinishDate'). This field is ignored if Rule = 'None' or ApplyConstraint = 'N'. This field accepts positive, negative, and fractional values. For example, assuming a Rule of 'StartDate', an Offset of '3' means that the task cannot start earlier than three days after the supply's available date. Similarly, an Offset of '-2' means that the task cannot start earlier than two days before the supply's available date.	Quantity	
PartLink	A reference to the task and part relationship that associates the task with the part it requires. **Referenced table:** TaskPartLink	Reference	
ReceivedQuantity	The amount of the supply that has been already been received for the task.	Quantity	

Table 6.346: TaskSupplyLink (ProjMgmt) fields

Field name	Description	Data type	Key
Rule	Indicates how the availability of this supply constrains the task completion. Valid values are: • **FinishDate**—the task cannot finish any earlier than the supply's available date plus any applicable offset. Note that if **ApplyConstraint** is set to "N", then the task's finish date is not impacted by the constraint. • **None**—the task is not constrained by the supply available date. • **StartDate**—the task cannot start any earlier than the supply's available date plus any applicable offset. Note that if **ApplyConstraint** is set to "N", then the task's finish date is not impacted by the constraint. **Default value:** None For more information about how this field is used, see "Supply and demand order links" on page 2171.	String (Enum)	
ScheduledReceipt	A reference to a specific supply required to complete this task. **Referenced table:** ScheduledReceipt	Reference	Yes
Task	A reference to the task that has a supply dependency. **Referenced table:** Task	Reference	Yes

TaskSupplyLink table – calculated and set fields

The following describes the calculated and set fields in the TaskSupplyLink table. For an introduction to this table, and descriptions of its input fields, see "TaskSupplyLink table" on page 650.

Table 6.347: Calculated TaskSupplyLink (ProjMgmt) fields

Field name	Description	Data type	Key
CalcPercent Received	The percentage of this supply's assigned quantity that has already been received by the task.	Quantity	
Critical	Indicates if the supply's availability determines when the task can be completed.Valid values are: • N • Y	Boolean	
MaterialCost	The cost associated with the quantity of parts assigned to this task from the referenced supply. Based on the sum of all values reported for this record in the **TaskSupplyLinkCost** table.	Money	

TimePhasedDemandParameterSet table

The **TimePhasedDemandParameterSet** table is used to manually specify time-phased average and standard deviation of historical demands for a given safety stock item (part). These values can then be used as parameters in determining recommended safety stock levels on time-phased safety stock items. This table is intended for cases where there is limited historical demand data available for an item but the time-phased statistical parameters are known or estimated through some other means. Typically, one record should be specified for each period/season in a full cycle.

Table 6.348: TimePhasedDemandParameterSet(Mfg) fields

Field name	Description	Data type	Key
Average	Average historical demand for this item in the specified period (by index).	Quantity	
Id	A unique string identifier for this record.	String	Yes
Index	A zero-based index used to indicate the period or season to which this record's parameters apply within the full seasonal cycle. For example, if **CycleCalendar** is "Year" and **PeriodCalendar** is "Month", then 0 refers to January, 1 refers to February, and so on.	Integer	
SafetyStockItem	A reference to the safety stock item to which the parameters on this record apply. The values defined on this record are only used in safety stock calculations when this item references a **SafetyStockItemType** record that has **TimePhasedProcessingRule** set to "Use" and **NonStationaryDemandRule** set to "Manual". **Referenced table:** SafetyStockItem	Reference	Yes
StandardDeviation	Standard deviation of historical demand for this item in the specified period (by index).	Quantity	

TimePhasedLocationCapacity table

The **TimePhasedLocationCapacity** table is used to define the time-phased storage capacity of locations in a distribution network. The location in this table is referenced from the **Location** table. This table was added in the Version 2016.2, Service Update 5, to support the Distribution Requirements Planning application.

Table 6.349: TimePhasedLocationCapacity (Solutions) fields

Field name	Description	Data type	Key
Date	The date when this time-phased storage capacity record becomes effective.	Date	Yes
Location	The location for which this time-phased storage capacity record is specified. **Referenced table**: Location	Reference	Yes
StorageCapacity	The time-phased storage capacity quantity specified for the location.	Quantity	
StorageCapacity UOM	Defines the unit of measure used for the location. **Referenced table**: UnitofMeasure	Reference	

TimePhasedMaximumInventory table

The **TimePhasedMaximumInventory** table is used to set the maximum inventory quantity for a part. If a part has the **DistributionPlanningRule.ProcessingRule** set to **Enable** and the part exceeds the set maximum inventory level at the sourcing site, this triggers a request for the finished goods to be transferred (pushed) to a destination site before it is required.

This table was added in Version 2016.2.

Table 6.350: TimePhasedMaximumInventory (Mfg) fields

Field name	Description	Data type	Key
Part	The name of the part for which the maximum inventory level is set. **Referenced table**: Part	Reference	Yes
Pool	A reference to the pool for the part. **Referenced table**: Pool	Reference	Yes
Date	Date when the maximum inventory value for the part becomes effective.	Date	Yes
Quantity	The amount of the maximum inventory that is set for the part starting on the Date. This value is reported in the unit of measure used by the part.	Quantity	

TimePhasedPartSourceLeadTime table

The **TimePhasedPartSourceLeadTime** table can be used to define time-phased lead time parameters at the part source level. For example, if fixed or dock-to-stock lead time values are expected to change over

time, this table can be used to hold those values.

Each record in this table applies to a given **PartSource** as of a specified **EffectiveInDate** and remains effective until the next **EffectiveInDate** found on a record for that same **PartSource**. When determining which set of lead time values apply to a given supply from the part source, the record with the nearest **EffecitveInDate** on or before the **PlannedOrder.ParameterDate** or **ScheduledReceipt.ParameterDate** is used. When this table is not used, or if it does not contain an effective record for a part source in a given period, the default **FixedLeadTime** and **DockToStockLeadTime** values from the **PartSource** table are used instead.

This table was added in Version 2016.2, Service Update 18. A **UseTimePhasedPartSourceLeadTime** field was also added to the **PartSourceType** table to give further control over whether values added to this table are used in lead-time calculations.

Table 6.351: TimePhasedPartSourceLeadTime(Mfg) fields

Field name	Description	Data type	Key
DockToStockLeadTime	The time required to move materials from the receiving dock to available inventory. Expressed in **Part.PlanningCalendars.TimeUnits** calendar intervals. **NOTE**: A negative value indicates to use the **DockToStockLeadTime** value from the previous (next earliest) record.	Quantity	
EffectiveInDate	The date on which the lead time values defined on this record become effective for the part source.	Date	Yes
FixedLeadTime	A fixed amount of time to produce each order for the part from this source. Expressed in **PartSource.Source.LeadTimeUnit** calendar intervals. **NOTE**: A negative value indicates to use the **FixedLeadTime** value from the previous (next earliest) record.	Quantity	
PartSource	The part source to which the time-phased lead time values on this record apply. **Referenced table**: PartSource	Reference	Yes

TimePhasedSafety table

The **TimePhasedSafety** table contains date and quantity values used to determine time-phased safety stock quantities for parts with certain **SafetyStockQuantityRule** settings (as defined on the applicable **SafetyStockPolicy** or **PartType** record).

For parts where the effective **SafetyStockQuantityRule** is set to either "TimePhasedQuantity" or "TimePhasedQuantityToLatest", this table is used to set the actual safety stock quantities that becomes effective on specified dates.

For parts where the effective **SafetyStockQuantityRule** is set to “TimePhasedRangeOfCoverage”, this table is used to define the number of days of the average daily requirement used in calculating the safety stock quantities within range of coverage zones that begin on specified dates.

Note that **TimePhasedRangeOfCoverage** does not calculate dynamic safety stock for the last period of demand if there is no future demand. For example, it is expected for RapidResponse to recalculate the safety stock level in April 2016 and drop it to zero. Inserting a new TimePhasedSafety record for 08-01-2016 doesn't impact the calculation. Changing the date on the new record to 04-01-2016 when the last demand is due, drops the SS level to zero, as expected.

For parts where the effective **SafetyStockQuantityRule** is set to either “TimePhasedSafetyDaysTotal” or “TimePhasedSafetyDaysMaximum”, this table is used to set the number of days of demand and a quantity that are used in calculating safety stock as of a specified date. Note these two settings are only available on the **SafetyStockPolicy** table (not included as options in **PartType.SafetyStockQuantityRule**).

For more information about using this table, see "Time-phased safety stock" on page 1403, or "Time-phased safety days" on page 1407, or "RangeOfCoverage calculations" on page 1409.

Table 6.352: TimePhasedSafety (Mfg) fields

Field name	Description	Data type	Key
Date	The date on which the safety stock quantity defined by this record becomes effective. The actual usage of this field depends on the **SafetyStockQuantityRule** setting as follows: • **TimePhasedSafetyDaysMaximum**—the date on which the values in the Days and Quantity fields become effective for use in calculating safety stock levels as the maximum of collected demands and specified quantity. • **TimePhasedSafetyDaysTotal**—the date on which the values in the Days and Quantity fields become effective for use in calculating safety stock levels as the sum of collected demands and specified quantity. • **TimePhasedQuantity**—the date on which the value in the **Quantity** field becomes effective as the safety stock level. • **TimePhasedQuantityToLatest**—the date on which the value in the **Quantity** field becomes effective as the safety stock level. • **TimePhasedRangeOfCoverage**—beginning of the range of coverage zone where the value in the **Days** field is used in calculating the safety stock quantity.	Date	

Table 6.352: TimePhasedSafety (Mfg) fields

Field name	Description	Data type	Key
Days	Number of days ahead to look when collecting demands for use in calculating dynamic safety stock levels. The specific usage of this field depends on the **SafetyStockQuantityRule** setting as follows: • **TimePhasedSafetyDaysMaximum**— the **SafetyStockPolicy.SafetyDaysCalendar** intervals ahead to collect demands for use in calculating the safety stock level (the maximum of the sum of collected demands and **Quantity** becomes the safety stock level on a given date). • **TimePhasedSafetyDaysTotal**—the number of **SafetyStockPolicy.SafetyDaysCalendar** intervals ahead to collect demands for use in calculating the safety stock level (the total of the sum of collected demands and **Quantity** becomes the safety stock level on a given date). • **TimePhasedQuantity**—this field is ignored. • **TimePhasedQuantityToLatest**—this field is ignored. • **TimePhasedRangeOfCoverage**— the number of days of the average daily requirement that calculated safety stock levels should satisfy within the zone that begins on the date defined in the **Date** field. **Note:** If a fractional quantity is specified when using either **TimePhasedSafetyDaysTotal** or **TimePhaseSafetyDaysMaximum**, the fractional amount indicates the percentage of demand to use from the last day being considered (for example, a value of 2.4 means to take the next two days of demand, plus forty percent of the demand in the third day). **Note:** If a negative value is specified when using either **TimePhasedSafetyDaysTotal** or **TimePhasedSafetyDaysMaximum**, then the previous (non-negative) Days value defined on a record for the part is used. **Note:** The **TimePhasedSafetyDaysTotal** and **TimePhasedSafetyDaysMaximum** options referred to above are not supported if using the legacy **PartType** settings for safety stock quantity.	Quantity	

Table 6.352: TimePhasedSafety (Mfg) fields

Field name	Description	Data type	Key
OrderPriority	The priority to assign to this safety stock requirement. If this field is left Null and **SafetyStockPolicy.DemandTransformationRule** is set to "Ignore", the part's default priority from **PartType.DefaultPriority** is used instead (if the **DemandTransformationRule** is set to "FirstInFirstOut" then prioritized safety stock should not be used). When the part's **SafetyStockPolicy.CTPHoldRule** is set to "Use", this priority determines how maintaining the safety stock requirement is prioritized against actual demands. When there is limited supply available to satisfy all demands, safety stock requirements are preferred to actual demands of the same or lower priority. As a result, supply allotments to lower-priority demands can be temporarily held to ensure safety stock levels are maintained. Note that Also that if a part has multiple safety stock requirements at different priority levels, each is handled separately. That is, an increase or decrease in the safety stock level at a given priority does not affect or change the part's safety stock levels at any other priorities. **Referenced table**: OrderPriority (Nullable) **NOTE**: This field was added in Version 2016.2, Service Update 18. It is supported for use with the **SafetyStockQuantityRule** of "TimePhasedQuantity" (other settings such as "TimePhasedSafetyDaysMaximum" and "TimePhasedSafetyDaysTotal" are not supported). For more information about how priorities on safety stock are used in capable-to-promise logic, see "Priority and safety stock holds in CTP" on page 1780	Reference	
Part	The Part this record applies to. **Referenced table:** Part **Reference Syntax**: Part.Name, Part.Site	Reference	
Pool	Indicates the pool in which the part's safety stock quantity should be planned. Applicable only when pooling logic is enabled and **MUEPoolNettingType.SafetyStockRule** is set to "ByPool". If this reference is null, the safety stock quantity is planned in the common pool. **Referenced table**: Pool (Nullable)	Reference	

Table 6.352: TimePhasedSafety (Mfg) fields

Field name	Description	Data type	Key
Quantity	The safety stock quantity that becomes effective on the date specified in the **Date** field. The actual usage of this field depends on the **SafetyStockQuantityRule** setting as follows: • **TimePhasedSafetyDaysMaximum**—the quantity compared against the sum of demands collected over some of forward-looking intervals (as set by the **Days** field) to determine the safety stock level on a given day (the maximum of these two values is used). • **TimePhasedSafetyDaysTotal**—the quantity added to the sum of demands collected over some number of forward-looking intervals (as set by the **Days** field) to determine the safety stock level on a given day (the total of these two values is used). • **TimePhasedQuantity**—the actual safety stock quantity that becomes effective on the specified date. • **TimePhasedQuantityToLatest**—the actual safety stock quantity that becomes effective on a specified date (excepting situations where the safety stock level decreases after the last demand for the part). • **TimePhasedRangeOfCoverage**—this field is ignored. **Note:** If a negative value is specified when using either **TimePhasedSafetyDaysTotal** or **TimePhasedSafetyDaysMaximum**, then the previous (non-negative) **Quantity** value defined on a record for the part is used. **Note:** The **TimePhasedSafetyDaysTotal** and **TimePhasedSafetyDaysMaximum** options referred to above are not supported if using the legacy **PartType** settings for safety stock quantity.	Quantity	

TimePhasedSourceLeadTime table

The **TimePhasedSourceLeadTime** table can be used to define time-phased lead time parameters at the source level. For example, if transit time or pre-ship lead time values are expected to change over time, this table can be used to hold those values.

Each record in this table applies to a given **Source** as of a specified **EffectiveInDate** and remains effective until the next **EffectiveInDate** found on a record for that same **Source**. When determining which set of lead time values apply to a given supply from the part source, the record with the nearest **EffecitveInDate** on or before the **PlannedOrder.ParameterDate** or **ScheduledReceipt.ParameterDate** is used. When this table is not used, or if it does not contain an effective record for a source in a given period, the default **PreShipLT**and **TransitTime** values from the **Source** table are used instead.

This table was added in Version 2016.2, Service Update 18. A **UseTimePhasedSourceLeadTime** field was also added to the **PartSourceType** table to give further control over whether values added to this table are used in lead-time calculations.

Table 6.353: TimePhasedSourceLeadTime (Mfg) fields

Field name	Description	Data type	Key
EffectiveInDate	The date on which the lead time values defined on this record become effective for the source.	Date	Key
Source	The source to which the time-phased lead time values on this record apply. **Referenced table**: Source	Reference	Key
PreShipLT	The amount of time needed collect the inventory at the sourcing site and prepare it for shipment to the destination site. Should be expressed in **Source.LeadTimeUnits** calendar intervals. **NOTE**: A negative value indicates to use the **PreShipLT** value from the previous (next earliest) record.	Quantity	
TransitTime	The amount of time required to ship supply from the sourcing site to the destination site. Should be expressed in **Source.TransitCalendar** intervals (or Everyday calendar units if the **TransitCalendar** reference is Null). **NOTE**: A negative value indicates to use the **TransitTime** value from the previous (next earliest) record.	Quantity	

TimePhasedYield table

The **TimePhasedYield** table can be used to define time-phased yield and coproduct yield values. For example, the part source for a new product might have a certain yield when the product is introduced and then higher yields at later points in time as production processes improve.

Each record in this table applies to a given **PartSource** as of a specified **EffectiveInDate** and remains effective until the next **EffectiveInDate** found on a record for that same **PartSource**. If this table is not used (or does not contain an effective record for a part source in a certain period), the default **Yield** and **CoProductYield** values from the **PartSource** table are used instead.

This table was added in Version 2016.2, Service Update 12. For more information about yield calculations, see "Yield" on page 1391

Table 6.354: TimePhasedYield (Mfg) fields

Field name	Description	Data type	Key
CoProduct Yield	The percentage of a primary product's supply production that is expected to actually end up as the primary product. The remainder is distributed between its co-products and by-products based on the **BillOfMaterial.QuantityPer** values on the records defining those co-product and by-product relationships.. This field respects the setting in the **OrderPolicy.YieldUsage** field, is applied after the **Yield** field, and is always considered by Netting calculations. If not using co-product and by-product logic in RapidResponse, this field should be set to 0 (to ensure the field is not used in Netting calculations). **NOTE**: A negative value indicates to use the **CoProductYield** value from the previous (next earliest) record.	Quantity	
EffectiveIn Date	The date on which the time-phased yield and/or co-product yield values on this record become effective for the part source.	Date	Yes
PartSource	The part source to which the time-phased yield and/or co-product yield values on this record apply. **Referenced table:** PartSource	Reference	Yes
Yield	The expected yield on supplies from this part source after consideration for scrap during production. New planned order quantities are subsequently inflated for yield while firm scheduled receipt quantities are reduced by yield. Note that the interpretation of the value in this field is affected by the **OrderPolicy.YieldUsage** setting for the part source. For example, if five percent of supply is expected to be lost as scrap and **YieldUsage** is set to "ScrapPercent", then this field should be set to "5", however if **YieldUsage** were set to "YieldFraction" then this field should be set to "0.95". **NOTE**: A negative value indicates to use the **Yield** value from the previous (next earliest) record.	Quantity	

TransferDestination table

The **TransferDestination** table is used to model and store routes for transferring inventory where you cannot specify a part source because it would cause a recursive relationship with an existing part source. For example, it could be used to transfer inventory to a site that is upstream in your distribution network.

This table was added in the Version 2016.2, Service Update 5, to support the Distribution Requirements Planning application.

Table 6.355: TransferDestination (Solutions) fields

Field name	Description	Data type	Key
Id	A string identifier for this transfer destination.	String	
Default	Indicates if this is a default transfer destination.	Boolean	
DockToStock LeadTime	The time required to move materials from the receiving dock to available inventory at the destination site. The setting in this field increases the effective lead time for all types of supply; ensure it is set to 0 unless needed. It is measured using **Part.PlanningCalendars.TimeUnits**. **Default value**: 0	Quantity	
Priority	The priority associated with this transfer destination.	Integer	
TransferCost	The cost that is specified for an inventory transfer that is using this transfer destination.	Money	
Part	The part for which this transfer destination exists. **Referenced table**: Part **Reference Syntax**: Part.Name, Part.Site	Reference	
Source	References the **Source** record that applies to the transfer destination record. **Referenced table**: Source	Reference	
TransferPart	References the **Part** record for the **Source** site that applies to the transfer destination. This field references the **Part** table. **Referenced table**: Part **Reference Syntax**: Part.Name, Part.Site	Reference	

TransportationMode table

The **TransportationMode** table defines different modes of transportation used to ship orders to customers or to ship transfer orders from one node to another in a distribution network. It is referenced by the **DeliveryRoute** and **Source** tables to indicate the method by which an order moves along a given route to the customer.

Table 6.356: TransportationMode(Mfg) fields

Field name	Description	Data type	Key
Description	A description of this mode of transportation.	String	
Value	A value that identifies this mode of transportation. For example, “Land” or “Rail”.	String	Yes
Carriers	Set of Carrier records that reference this value.	Set	
DeliveryRoutes	Set of DeliveryRoute records that reference this value.	Set	
Transportation Modes	Set of **TransportationMode** records that reference this value. **Note:** This field was added in Version 2016.2, Service Update 5.	Set	

UnitOfMeasureCategory table

The **UnitOfMeasureCategory** table is used to group categories of units. Typically units in the same category can be used to express numerical values at that scale. For example, a category might be mass, volume, or count.

Units that belong to a category are stored in the UnitOfMeasure table, including the relative ratio between the units in that category. For example: millimeters, centimeters, meters, and kilometers might be values for the category “Length”. For more information, see "UnitOfMeasure table" on page 931.

This table was added in Version 2016.2, Service Update 12.

Table 6.357: UnitOfMeasureCategory (Mfg) fields

Field name	Description	Data type	Key
Id	A value that identifies the category for a unit of measure.	String	Yes
Description	A description of the category.	String	

UnitOfMeasureCategory table – calculated and set fields

The following describes the calculated and set fields in the UnitofMeasureCategory table. For an introduction to this table, and descriptions of its input fields, see "UnitOfMeasureCategory table" on page 664.

Table 6.358: Calculated UnitOfMeasureCategory (Mfg) fields

Field name	Description	Data type	Key
UnitOfMeasures	Set of UnitOfMeasure records that reference this UnitOfMeasureCategory value.	Set	

Warehouse table

The **Warehouse** table stores Id and Name values for the warehouses used in identifying the locations for inventory.

This table's **Site** field is optional, and a system or data administrator can choose whether it uniquely identifies records in the table, or is ignored in queries, and not shown in insert definitions, dialog boxes, or the Data Sources and Mapping window.

Table 6.359: Warehouse (Mfg) fields

Field name	Description	Data type	Key
Id	An Id code for the warehouse. **Default value**: blank string	String	Yes
Name	The name of the Warehouse (not used in MRP calculations.) **Default value**: blank string	String	
Site	The site where this warehouse is located. This field is optional. **Referenced table:** Site	Reference	Yes

For more information about making the **Site** field optional, see "Modifying table and field properties" in the *RapidResponse Data Integration Guide*.

Warehouse table – calculated and set fields

The following describes the calculated and set fields in the Warehouse table. For an introduction to this table, and descriptions of its input fields, see "Warehouse table " on page 665.

Table 6.360: Calculated Warehouse (Mfg) fields

Field name	Description	Data type	Key
Locations	Set of Location records referencing this warehouse.	Set	

WBS table

The WBS table holds records that define hierarchical parent-child relationships between project tasks. Parent tasks are typically summary tasks, and child tasks are typically sub-tasks. A given task can have no more than one parent defined, and any tasks without a parent (that is, top-level tasks) are not shown in this table.

If using Task-based worksheets automatically configured for project management, such as in the **Project Plan** workbook included with RapidResponse records are automatically added to this table each time a new task is inserted.

Table 6.361: WBS (ProjMgmt) fields

Field name	Description	Data type	Key
Child	A reference to the child (sub) task in the parent-child relationship defined by this record. **Referenced table:** Task	Reference	Yes
Parent	A reference to the parent (summary) task in the parent-child relationship defined by this record. **Referenced table:** Task	Reference	

WBS table – calculated and set fields

The following describes the calculated and set fields in the WBS table. For an introduction to this table, and descriptions of its input fields, see "WBS table" on page 666.

Table 6.362: Calculated WBS (ProjMgmt) fields

Field name	Description	Data type	Key
IsRecursive	Indicates if a recursive relationship exists between the parent and child task. Valid values are • **N**—relationship is not recursive. • **Y**—relationship is recursive; the Parent task associated with this record is a descendant of the Child task through some other parent/child relationship(s) defined in this table.	Boolean	

WorkCenter table

The WorkCenter table describes a unique work center. The record includes the name, description, cost information, and a set of available capacity records for this work center.

Table 6.363: WorkCenter (Mfg) fields

Field name	Description	Data type	Key
Department	Department in which the work center resides. **Referenced table:** Department (this reference is nullable in new installations of RapidResponse 10.1 and later).	Reference	
Description	Description of the work center. **Default value**: blank string	String	
Name	The name of the work center. **Default value**: blank string	String	Yes
PlanningCalendars	Reference to a PlanningCalendars record that holds the work center's working calendar and run date. **Referenced table:** PlanningCalendars	Reference	
Site	The site that is associated with this work center. **Referenced table:** Site	Reference	Yes
StdLaborRunCost	Cost per standard hour for labor run time. **Default value**: 1	Money	
StdLaborSetupCost	Cost per standard hour for labor setup time.	Money	
StdMachineRun Cost	Cost per standard hour for machine run time. **Default value**: 1	Money	
StdMachineSetup Cost	Cost per standard hour for machine setup time. **Default value**: 1	Money	
Type	WorkCenter type and is a reference to the WorkCenterType table through the WorkCenterType.Value field. **Referenced table:** WorkCenterType	Reference	

WorkCenter table — calculated and set fields

The following describes the calculated and set fields in the WorkCenter table. For an introduction to this table, and descriptions of its input fields, see "WorkCenter table " on page 666.

Table 6.364: Calculated WorkCenter (Mfg) fields

Field name	Description	Data type	Key
Capacity	A set of Capacity records that describe the capacity for this work center.	Set	
LoadsDailyCurrent	A calculated set of LoadDailyCurrent records for this work center using the current due date.	Set	
LoadsDailyPlanned	A calculated set of LoadDailyPlanned records for this work center using the rescheduled scheduled receipt date.	Set	
LoadsDetailCurrent	A calculated set of LoadDetailCurrent records for this work center using the current due date.	Set	
LoadsDetailPlanned	A calculated set of LoadDetailPlanned records for this work center using the rescheduled scheduled receipt due date.	Set	
LoadWeeklyCurrent	A calculated set of LoadWeeklyCurrent records for this work center using the current due date.	Set	
LoadWeeklyPlanned	A calculated set of LoadWeeklyPlanned records for this work center using the rescheduled scheduled receipt due date.	Set	
Operations	A set of Operation records that use this work center.	Set	

CHAPTER 7: Control tables

Control tables contain rules and values that determine the calculations RapidResponse performs on input data, and hence the data produced in calculated tables. Control tables are configured during a RapidResponse deployment, and ensure that RapidResponse calculations emulate those found in your enterprise or host system. These initial settings can subsequently be modified by data or system administrators in RapidResponse. For simulation purposes, worksheets based on RapidResponse Control tables can be modified on a scenarios-by-scenario basis.

Each control table contains a Value field that defines values that are used in the corresponding Type field of the base table. For example, the **Type** field in the **Part** table references the **Value** field in the **PartType** table.

In addition to control tables, certain RapidResponse calculations can be configured using global settings. For more information, see "Configuring analytic calculations using global settings" on page 2203.

In this chapter, you'll learn about the following:

AggregatePartCustomerType table **670**
AllotmentOverrideType table **671**
AlternatePartType table **672**
AnalyticsConfiguration table **674**
AttributeMapType table **676**
AutomatedLeadTimeType table **678**
AutomatedYieldType table **683**
AvailableRule table **686**
BOMType table **687**
Calendar table **695**
CalendarDate table **700**
ConstraintType table **700**
ConstraintUnitOfMeasure table **703**
CRPUnitOfMeasure table **704**
DaysSupplyPolicy table **705**
DemandStatus table **713**
DemandType table **715**
DDMRPRule table **721**
DistributionPlanningRule table **722**
DRPConfiguration table **724**
ExpiryType table **726**
ForecastItemParametersType table **727**
HistoricalDemandCategoryType table **736**
IMConfiguration table **739**

IncrementalRule table 741
InventoryTransferType table 741
IPOConfiguration table 743
MEIOLeadTimeType table 744
MPSConfiguration table 746
MUEPoolNettingType table 749
MultiEchelonSafetyStockRule table 756
MultiLevelSearchRule table 758
OFConfiguration table 767
OnHandType table 768
OperationSequenceType table 768
OperationType table 770
OrderPolicy table 773

SupplyType table 919
TaskType table 925
ToleranceProfile table 930
ToleranceProfileZone table 930
UnitOfMeasure table 931
WorkCenterType table 933

Caution: Because changes to control table settings can causes significant changes in the data generated by RapidResponse calculations (across all sites), you should exercise caution when working with control tables after the initial RapidResponse integration.

AggregatePartCustomerType table

The **AggregatePartCustomerType** table is used to enable or disable records in the **AggregatePartCustomer** table for processing when determining disaggregation rates.

Table 7.1: AggregatePartCustomerType (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this **AggregatePartCustomerType** record. **Referenced table:** ControlSet	Reference	Yes
Description	A description of this type.	String	
ProcessingRule	Indicates whether **AggregatePartCustomer** records that belong to this type are used in generating disaggregation rates. Valid values are: • **Ignore**—Aggregate part customers of this type are ignored during forecast disaggregation. That is, disaggregation is performed for detailed or individual part and customer combinations. • **Use**—Aggregate part customers of this type are considered during forecast disaggregation. That is, disaggregation is performed at the specified aggregate part-customer level.	String (Enum)	
Value	A unique string identifier for this type.	String	Yes
AggregatePart Customers	Set of **AggregatePartCustomer** records that belong to this type.	Set	

AllotmentOverrideType table

The **AllotmentOverrideType** table is referenced by the **AllotmentOverride** table and used to control processing of allotment overrides in RapidResponse calculations. Allotment overrides refer to specified quantities of lower-level components that are manually allotted to top-level supplies or demands. For example, allotment overrides might be used to manually allocate supply in cases where RapidResponse analytic calculations cannot easily achieve the desired allocation of limited components.

Table 7.2: AllotmentOverrideType (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this AllotmentOverrideType record. **Referenced table:** ControlSet	Reference	Yes
Description	Additional information describing this AllotmentOverrideType record.	String	

Table 7.2: AllotmentOverrideType (Mfg) fields

Field name	Description	Data type	Key
ProcessingRule	Controls whether AllotmentOverride records, and their associated AllotmentOverrideDetails values, are enabled or disabled in RapidResponse calculations. Valid values are: • **Always**—AllotmentOverride records of this type are always enabled. • **AfterRunDate**—AllotmentOverrideDetails records associated with AllotmentOverride records of this type are enabled or disabled based on date. If AllotmentOverrideDetail.Date is on or after RunDate, that record is enabled. Otherwise, if AllotmentOverrideDetails.Date is before RunDate, that record is disabled. • **Ignore**—AllotmentOverride records of this type are always disabled.	String (Enum)	
Value	A unique identifier for this AllotmentOverrideType record. This field is referenced from the **Type** field on the **AllotmentOverride** table.	String	Yes
Allotment Overrides	Set of **AllotmentOverride** records that reference this AllotmentOverrideType value.	Set	

AlternatePartType table

This table is referenced by the AlternatePart table, and is used to indicate if a PrimaryPart and AlternatePart combination represents an interchangeable part relationship or a substitute part relationship. It also contains several settings specific to substitute part calculations.

Table 7.3: AlternatePartType (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this AlternatePartType record. **Referenced table**: ControlSet	Reference	Yes
Description	Additional information describing this AlternatePartType value.	String	

Table 7.3: AlternatePartType (Mfg) fields

Field name	Description	Data type	Key
EffectivityRule	Determines how the EffectiveInDate and EffectiveOutDate fields on the AlternatePart record are used in substitute part calculations. Valid values are: • **Always**—the AlternatePart record is always effective. • **Exclusive**—the AlternatePart record is effective starting after the EffectiveInDate and ending before the EffectiveOutDate. • **Inclusive**—the AlternatePart record is effective starting on the EffectiveInDate and ending on the EffectiveOutDate. • **InclusiveExclusive**—the AlternatePart record is effective starting on the EffectiveInDate and ending before the EffectiveOutDate. • **Never**—the AlternatePart record is never effective. **Default value:** InclusiveExclusive **Note:** If the AlternatePart record defines an interchangeable part relationship, then it is always considered effective (regardless of the setting in this field or the EffectiveInDate/EffectiveOutDate value.	String (Enum)	
PoolRule	Indicates if the Pool value on the AlternatePart record is used in substitute part calculations. Valid values are: • **Ignore**—the Pool value on the AlternatePart table is ignored. • **Use**—the Pool value on the AlternatePart table is used (for customer-specific part substitution). **Default value**: Ignore	String (Enum)	

Table 7.3: AlternatePartType (Mfg) fields

Field name	Description	Data type	Key
ProcessingRule	Controls whether the pair of parts in the AlternatePart record have an interchangeable part relationship or a substitute part relationship. Valid values are: • **Ignore**—the part relationship is ignored. • **Interchangeable**—the parts are considered equivalent in fit, form, and function. The PrimaryPart and SubstitutePart are interchangeable, and demand for one can be satisfied by supply of the other. No preference is given as to which part's supply satisfies a demand. All planned orders and calculated results in an interchangeable relationship are generated for the **PrimaryPart** only. However, in order to be used in an interchangeable relationship, the **SubstitutePart** still requires at least one effective PartSource record (can include sources whose **OrderPolicy.OrderGenerationRule** is set to "NoOrders"). • **Substitute**—one part is considered a substitute for the other. Demand for the PrimaryPart can be satisfied by the SubstitutePart, however demand for the SubstitutePart cannot be satisfied by the PrimaryPart. Whenever possible, demand for the PrimaryPart will be satisfied by its own supply (that is supply of the SubstitutePart is only used when not enough of the PrimaryPart is available). However, planned orders and calculated results in a substitute relationship can be generated for both the PrimaryPart and SubstitutePart. **Default value**: Interchangeable	String (Enum)	
Value	A unique string identifier for this AlternatePartType record.	String	Yes
AlternateParts	Set of **AlternatePart** records that reference this AlternatePartType value.	Set	

AnalyticsConfiguration table

The **AnalyticsConfiguration** table is used to set global, scenario-based parameters that primarily apply to multi-echelon safety stock calculations. The **Inventory Planning Settings** worksheet in the **Inventory Planning** workbook included with RapidResponse can be used to edit values this table.

Because the underlying analytic uses an iterative approach to determine optimal safety stock levels, multiple iterations through a family of related parts can be expected in order to determine the best solution. Records in this table thus allow for practical limits to be placed on how long the multi-echelon analytic can potentially be run in search of the optimal solution (large families of parts typically take longer amounts of time for the analytic to process). If this table does not contain a record in a given scenario, then multi-echelon calculations within that scenario will run with values set to 500 iterations for **MEIOMaximumIterations** and 5 minutes for **MEIOMaximumTime**.

Table 7.4: AnalyticsConfiguration (Mfg) fields

Field name	Description	Data type	Key
MEIOAllowSafetyStockOnArtificialStages	When this field is set to "N" or there are records in the **SafetyStockTimePhasedBounds** table, safety stock is not allowed on artificial stages during multi-echelon inventory optimization. When this field is set to "Y" and there are no records in the **SafetyStockTimePhasedBounds** table, safety stock is allowed on artificial stages during multi-echelon inventory optimization. This might result in slightly lower safety stock recommendations. To edit the value of this field using the **Inventory Planning Settings** worksheet, all records must first be removed from the **SafetyStockTimePhasedBounds** table in the active scenario. **Default value:** "N" **Note:** This field was added in Version 2016.2.	Boolean	
MEIOFutureDemandInterval Count	Number of calendar intervals to collect future demands and calculate average demands for use in calculations reported in the **SafetyStockResult** and **SafetyStockTimePhasedResult** table. Note that these tables report calculated results from both single-echelon planning and multi-echelon inventory optimization calculations. **Note:** This field was added in Version 2014.4	Integer	
MEIOMaximum Iterations	Maximum number of iterations the analytic can make through a network of parts to determine the optimal levels of safety stock to hold across all parts in the network. If the best solution is found before the number of iterations specified, the analytic stops regardless. **Note:** Significant improvements in results are not typically found beyond 500 iterations.	Integer	
MEIOMaximum Time	Maximum amount of time (in minutes) the analytic can spend iterating through a network of parts to determine the optimal levels of safety stock to hold across all parts in the network. If the best solution is found before the number of minutes specified, the analytic stops regardless.	Integer	

Table 7.4: AnalyticsConfiguration (Mfg) fields

Field name	Description	Data type	Key
MEIOReport Calendar	If generating time-phased safety stock calculations, this specifies the calendar containing the dates on which safety stock results are generated. For example, if set to a Month calendar then safety stock can only be calculated on dates marking the beginning of a Monthly calendar (if no calendar is specified then an Everyday calendar is assumed). Note that the number of date markers in the selected calendar can impact the processing time taken to generate time-phased results. For example, it would take less time to generate results for each month than it would take to generate results for each day. **Referenced table:** Calendar (nullable)	Reference	
MEIOReport IntervalCount	Number of calendar intervals to report calculated results in the SafetyStockTimePhasedResult table. Note that this field reports calculated results from both single-echelon planning and multi-echelon inventory optimization calculations. **Note:** This field was added in Version 2014.4	Integer	
MLSTrialLimitPer Demand	The maximum number of trials that the multi-level search analytic can perform in search of the best path to satisfy a demand. **Default value**: 50000	Integer	

AttributeMapType table

The **AttributeMapType** table is referenced by the **AttributeMap** table and defines how the attribute rules on that table are interpreted and processed. Each record in this table can be configured to enable or disable attribute rules for use in supply allocation, forecast consumption, and/or forecast adjustment calculations.

This table is not shown in the *RapidResponse Data Model for Import* poster.

Table 7.5: AttributeMapType (Core) fields

Field name	Description	Data type	Key
Description	A description of this attribute map type.	String	
Forecast Adjustment	Specifies whether AttributeMap records of this type are considered when specifying adjustments or overrides on ForecastDetail records used in generating the S&OP consensus forecast. For example, adjustments or overrides might only be applied within a specific forecast category for a given part customer. Valid values are • **N**—AttributeMap records of this type are ignored when making adjustments or overrides on ForecastDetail records. • **Y**—AttributeMap records of this type are considered when making adjustments/overrides on ForecastDetail records. Typically, if using sales and operations planning in RapidResponse and either or both of the **ForecastConsumption** or **SupplySelection** fields are set to "Y", then this field should be set to "Y" as well. This ensures adjustments are made within matching combinations of attributes on **ForecastDetail** values and not mixed together. **Default value:** N **Caution:** If the same demand attribute is defined in two or more **AttributeMap** rules that reference **AttributeMapType** records with different values in thisfield, then all of those rules are treated as though **ForecastAdjustment** is set to "Y" (that is, a "Y" setting overrides any "N" settings).	Boolean	

Table 7.5: AttributeMapType (Core) fields

Field name	Description	Data type	Key
Forecast Consumption	Specifies whether AttributeMap records of this type are considered during the forecast consumption process. When attribute-based forecast consumption is enabled, then in order to consume a specific forecast, all enabled attribute values on an actual demand must match the corresponding attribute values on the forecast demand. For example, a given customers forecast might only be eligible to be consumed by actual demands from that same customer. Valid values are • **N**—AttributeMap records of this type are ignored during forecast consumption. • **Y**—AttributeMap records of this type are considered during forecast consumption. **Default value:** N **Note:** When this field is set to "Y", then the **MUEPoolNettingType**.**AttributeFlowToCommon** field can be used to set whether actual demands with specific attribute values can, after consuming all forecast demands with matching attribute values, begin to consume forecasts that do not have any attribute values defined or enabled.	Boolean	
SupplySelection	Specifies whether AttributeMap records of this type are considered when allocating supplies to demands. If attribute-based supply allotment is enabled, then only specific on hand inventory, scheduled receipts, and part sources might be eligible for use in satisfying particular independent, consensus forecast, and/or safety stock demands. For example, a given customer's demands might only accept supplies sourced from particular locations or manufacturing facilities. Valid values are • **N**—AttributeMap records of this type are ignored when allocating supply to demand. • **Y**—AttributeMap records of this type are considered when allocating supply to demand. **Default value**: N	Boolean	
Value	A unique identifier for this **AttributeMapType** record. This field is referenced from the **Type** field on the **AttributeMap** table.	String	Yes
AttributeMaps	Set of **AttributeMap** records that reference this **AttributeMapType** value.	Set	

AutomatedLeadTimeType table

The **AutomatedLeadTimeType** table contains control settings that define how the lead time corrections projected by the Machine Learning server are processed for **ItemSource** records of a

particular type.

For example, the zone threshold fields (**NearToleranceThreshold** and **OutsideToleranceThreshold**) determine which tolerance zone the lead time deviations for an **ItemSource** belong to (whether the **ItemSource** is defined as "inside tolerance", "near tolerance", or "outside tolerance"). Based on the lead time tolerance zones defined by the zone thresholds, the zone policy fields (**InsideToleranceAction**, **NearToleranceAction**, and **OutsideToleranceAction**) control whether the projected lead times are meant to be automatically accepted, manually reviewed, or ignored.

For more information about how lead time deviations are calculated, see "Self-Healing Supply Chain calculations" on page 2146.

This table was added in Version 2016.2, Service Update 21.

Table 7.6: AutomatedLeadTimeType (Mfg) fields

Field name	Description	Data type	Key
HistoricalLeadTimeErrorMeasure	The error measure to report in **ItemSource.CalcHistoricalLeadTimeError**. Note that this field determines the units of the **NearToleranceThreshold** and **OutsideToleranceThreshold** fields. Valid values are: • **MeanAbsoluteDeviation** —Determines the absolute value of variance between the historical supply actual values and the "as designed" forecast values, expressed as **LeadTimeUnit**. The calculation is represented by the following equation: $\mathbf{MAD} = \frac{1}{n} \sum_{i=1}^{n} \lvert \mathbf{ActualLeadTime}_i - \mathbf{PartSourceLeadTime}_i \rvert$ • **MeanAbsolutePercentageError** —Determines the absolute value of variance between the historical supply actual values and the "as designed" forecast values, expressed as a percentage. The calculation is represented by the following equation: $\mathbf{MAPE} = \frac{1}{n} \sum_{i=0}^{n} \frac{\lvert \mathbf{ActualLeadTime}_i - \mathbf{PartSourceLeadTime}_i \rvert}{\mathbf{ActualLeadTime}_i}$ where: ◦ n is the number of **ItemSourcePartSourceHistoricalLeadTime** records for a given **ItemSource**. ◦ $\mathbf{ActualLeadTime}_i$ is **ItemSourcePartSourceHistoricalLeadTime.ActualLeadTime**. ◦ $\mathbf{PartSourceLeadTime}_i$ is **ItemSourcePartSourceHistoricalLeadTime.PartSourceLeadTime**. **Default value:** MeanAbsoluteDeviation **Note:** If there are no historical supply actuals in the historical horizon, then **MeanAbsolutePercentageError** reports 0.	Enum	
InsideToleranceAction	The action to be taken when lead time deviation falls inside the defined **NearToleranceThreshold**. Valid values are: • **AutoAccept** —Automatically accepts the projected lead times and copies the lead time changes to the **TimePhasedPartSourceLeadTime** table. • **Ignore** —Ignores the projected lead times. • **Review** —Flags the projected lead times for manual review to determine whether to ignore or accept the suggestions. **Default value:** Ignore **Note:** Ignore is the recommended setting.	Enum	

Table 7.6: AutomatedLeadTimeType (Mfg) fields

Field name	Description	Data type	Key
NearToleranceAction	The action to be taken when lead time deviation falls in between the **NearToleranceThreshold** and **OutsideToleranceThreshold**. Valid values are: • **AutoAccept** —Automatically accepts the projected lead times and copies the lead time changes to the **TimePhasedPartSourceLeadTime** table. • **Ignore** —Ignores the projected lead times. • **Review** —Flags the projected lead times for manual review to determine whether to ignore or accept the suggestions. **Default value:** Ignore **Note:** AutoAccept is the recommended setting.	Enum	
NearToleranceThreshold	The tolerance threshold that defines the tolerance zones for the lead time deviations. The value for this threshold is defined by the **HistoricalLeadTimeErrorMeasure**. If the lead time deviation (**ItemSource.CalcHistoricalLeadTimeError**) is less than the **NearToleranceThreshold**, then the **ItemSource** is considered to be "inside tolerance". In this case, the **InsideToleranceAction** is used. If the lead time deviation is more than or equal to the **NearToleranceThreshold** but less than the **OutsideToleranceThreshold**, then the **ItemSource** is considered to be "near tolerance". In this case, the **NearToleranceAction** is used. **Note:** Only positive number values should be used for the threshold settings (values less than zero are treated as zero). **Note:** If the **NearToleranceThreshold** is more than the **OutsideToleranceThreshold** , then **ItemSource.CalcLeadTimeZone** = "None". In this case, the cell for the **OutsideToleranceThreshold** will be conditionally formatted with a yellow background and bold red text in the Automated Lead Time Type worksheet of the Control Tables workbook.	Quantity	

Table 7.6: AutomatedLeadTimeType (Mfg) fields

Field name	Description	Data type	Key
OutsideToleranceAction	The action to be taken when lead time deviation falls outside the defined **OutsideToleranceThreshold**. Valid values are: • **AutoAccept** —Automatically accepts the projected lead times and copies the lead time changes to the **TimePhasedPartSourceLeadTime** table. • **Ignore** —Ignores the projected lead times. • **Review** —Flags the projected lead times for manual review to determine whether to ignore or accept the suggestions. **Default value:** Ignore **Note:** Review is the recommended setting.	Enum	
OutsideToleranceThreshold	The tolerance threshold that defines the tolerance zones for the lead time deviations. The value for this threshold is defined by the **HistoricalLeadTimeErrorMeasure**. If the lead time deviation (**ItemSource.CalcHistoricalLeadTimeError**) is more than or equal to the **OutsideToleranceThreshold**, then the **ItemSource** is considered to be "outside tolerance". In this case, the **OutsideToleranceAction** is used. **Note:** Only positive number values should be used for the threshold settings (values less than zero are treated as zero). **Note:** If the **OutsideToleranceThreshold** is less than the **NearToleranceThreshold**, then **ItemSource.CalcLeadTimeZone** = "None". In this case, the cell for the **OutsideToleranceThreshold** will be conditionally formatted with a yellow background and bold red text in the Automated Lead Time Type worksheet of the Control Tables workbook.	Quantity	
ProcessingRule	Specifies how to process the projected lead times for the **ItemSource**. You can use this setting to override the tolerance actions. Valid values are: • **Ignore** —Does not run the Machine Learning service. • **Manual** —Equivalent to setting all tolerance actions to "Review". • **UseZonePolicy** —Uses the settings specified for the **InsideToleranceAction**, **NearToleranceAction**, and **OutsideToleranceAction** fields. **Default value:** Ignore **Note:** UseZonePolicy is the recommended setting.	Enum	

Table 7.6: AutomatedLeadTimeType (Mfg) fields

Field name	Description	Data type	Key
Value	A unique string identifier for the **AutomatedLeadTimeType** record. This value is referenced from the **ItemSource.AutomatedLeadTimeType** field.	String	Yes
ItemSources	Set of **ItemSource** records that reference this **AutomatedLeadTimeType**. **Referenced table:** "ItemSource table" on page 379	Set	

AutomatedYieldType table

The **AutomatedYieldType** table contains control settings that define how the yield corrections projected by the Machine Learning server are processed for **ItemSource** records of a particular type.

For example, the zone threshold fields (**NearToleranceThreshold** and **OutsideToleranceThreshold**) determine which tolerance zone the yield deviations for an **ItemSource** belong to (whether the **ItemSource** is defined as "inside tolerance", "near tolerance", or "outside tolerance"). Based on the yield tolerance zones defined by the zone thresholds, the zone policy fields (**InsideToleranceAction**, **NearToleranceAction**, and **OutsideToleranceAction**) control whether the projected yields are meant to be automatically accepted, manually reviewed, or ignored.

For more information about how yield deviations are calculated, see "Self-Healing Supply Chain calculations" on page 2146.

Table 7.7: AutomatedYieldType (Mfg) fields

Field name	Description	Data type	Key
HistoricalYieldErrorMeasure	The error measure to report in **ItemSource.CalcHistoricalYieldError**. Note that this field determines the units of the **NearToleranceThreshold** and **OutsideToleranceThreshold** fields. Valid values are: • **MeanAbsoluteDeviation** —Determines the absolute value of variance between the historical receipts values and the "as designed" forecast values, expressed as **YieldUnit**. The calculation is represented by the following equation: $\mathrm{MAD} = \frac{1}{n} \sum_{i=1}^{n} \lvert \mathrm{ActualYield}_i - \mathrm{PartSourceYield}_i \rvert$ • **MeanAbsolutePercentageError** —Determines the absolute value of variance between the historical receipts values and the "as designed" forecast values, expressed as a percentage. The calculation is represented by the following equation: $\mathrm{MAPE} = \frac{1}{n} \sum_{i=0}^{n} \frac{\lvert \mathrm{ActualYield}_i - \mathrm{PartSourceYield}_i \rvert}{\mathrm{ActualYield}_i}$ where: ◦ n is the number of **ItemSourcePartSourceHistoricalReceipt** records for a given **ItemSource**. ◦ $\mathrm{ActualYield}_i$ is **ItemSourcePartSourceHistoricalReceipt.EffectiveHistoricalYield**. ◦ $\mathrm{PartSourceYield}_i$ is **ItemSourcePartSourceHistoricalReceipt.PartSourceYield**. **Default value:** MeanAbsoluteDeviation **Note:** If there are no historical supply actuals in the historical horizon, then **MeanAbsolutePercentageError** reports 0.	Enum	
InsideToleranceAction	The action to be taken when yield deviation falls inside the defined **NearToleranceThreshold**. Valid values are: • **AutoAccept** —Automatically accepts the projected yields and copies the yield changes to the **TimePhasedPartSourceYield** table. • **Ignore** —Ignores the projected yields. • **Review** —Flags the projected yields for manual review to determine whether to ignore or accept the suggestions. **Default value:** Ignore **Note:** Ignore is the recommended setting.	Enum	

Table 7.7: AutomatedYieldType (Mfg) fields

Field name	Description	Data type	Key
NearToleranceAction	The action to be taken when yield deviation falls in between the **NearToleranceThreshold** and **OutsideToleranceThreshold**. Valid values are: • **AutoAccept** —Automatically accepts the projected yields and copies the yield changes to the **TimePhasedPartSourceYield** table. • **Ignore** —Ignores the projected yields. • **Review** —Flags the projected yields for manual review to determine whether to ignore or accept the suggestions. **Default value:** Ignore **Note:** AutoAccept is the recommended setting.	Enum	
NearToleranceThreshold	The tolerance threshold that defines the tolerance zones for the yield deviations. The value for this threshold is defined by the **HistoricalYieldErrorMeasure**. If the yield deviation (**ItemSource.CalcHistoricalYieldError**) is less than the **NearToleranceThreshold**, then the **ItemSource** is considered to be "inside tolerance". In this case, the **InsideToleranceAction** is used. If the yield deviation is more than or equal to the **NearToleranceThreshold** but less than the **OutsideToleranceThreshold**, then the **ItemSource** is considered to be "near tolerance". In this case, the **NearToleranceAction** is used. **Note:** Only positive number values should be used for the threshold settings (values less than zero are treated as zero). **Note:** If the **NearToleranceThreshold** is more than the **OutsideToleranceThreshold** , then **ItemSource.CalcYieldZone** = "None". In this case, the cell for the **OutsideToleranceThreshold** will be conditionally formatted with a yellow background and bold red text in the Automated Yield Type worksheet of the Control Tables workbook.	Quantity	
OutsideToleranceAction	The action to be taken when yield deviation falls outside the defined **OutsideToleranceThreshold**. Valid values are: • **AutoAccept** —Automatically accepts the projected yields and copies the yield changes to the **TimePhasedPartSourceYield** table. • **Ignore** —Ignores the projected yields. • **Review** —Flags the projected yields for manual review to determine whether to ignore or accept the suggestions. **Default value:** Ignore **Note:** Review is the recommended setting.	Enum	

Table 7.7: AutomatedYieldType (Mfg) fields

Field name	Description	Data type	Key
OutsideToleranceThreshold	The tolerance threshold that defines the tolerance zones for the yield deviations. The value for this threshold is defined by the **HistoricalYieldErrorMeasure**. If the yield deviation (**ItemSource.CalcHistoricalYieldError**) is more than or equal to the **OutsideToleranceThreshold**, then the **ItemSource** is considered to be "outside tolerance". In this case, the **OutsideToleranceAction** is used. **Note:** Only positive number values should be used for the threshold settings (values less than zero are treated as zero). **Note:** If the **OutsideToleranceThreshold** is less than the **NearToleranceThreshold**, then **ItemSource.CalcYieldZone** = "None". In this case, the cell for the **OutsideToleranceThreshold** will be conditionally formatted with a yellow background and bold red text in the Automated Yield Type worksheet of the Control Tables workbook.	Quantity	
ProcessingRule	Specifies how to process the projected yields for the **ItemSource**. You can use this setting to override the tolerance actions. Valid values are: • **Ignore** —Does not run the Machine Learning service. • **Manual** —Equivalent to setting all tolerance actions to "Review". • **UseZonePolicy** —Uses the settings specified for the **InsideToleranceAction**, **NearToleranceAction**, and **OutsideToleranceAction** fields. **Default value:** Ignore **Note:** UseZonePolicy is the recommended setting.	Enum	
TimePhasedMinCOV	Determines whether the yield projected by the Machine Learning server in **ProjectedYield** is categorized as time-phased. If **TimePhasedMinCOV** is less than or equal to **ItemSource.CalcProjectedYieldCOV**, then **TimePhasedYield** is used instead of **PartSource.Yield**.	Quantity	
Value	A unique string identifier for the **AutomatedYieldType** record. This value is referenced from the **ItemSource.AutomatedYieldType** field.	String	Yes

AvailableRule table

The **AvailableRule** table is used to control how available dates for a part's supplies and demands are calculated. By default, available dates are determined using all applicable capable-to-promise rules. However, these rules can be ignored for parts that are considered unimportant in the calculation of availability (such as, vendor managed parts).

Note that values in this table are only used by parts that have their **Part.AvailableRule** reference field populated. Otherwise, if **Part.AvailableRule** is left null, a part's availability rule comes from **PartType.AvailableRule**.

Table 7.8: AvailableRule (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this AvailableRule record. **Referenced table:** ControlSet	Reference	Yes
Description	A description of this control setting.	String	
ProcessingRule	Specifies how the availability of a part's supplies and demands is calculated. Valid values are: • **FromType**—Available dates for supplies and demands of the part are calculated using the setting in **PartType.AvailableRule** (either "Ignore" or "Normal"). • **Ignore**—available date is calculated for each supply, but requirements are treated as if the dependent and independent demands had been covered by on hand supplies. This means that dependent requirements onto these parts are available at Past and independent requirements are available at DataDate. Typically, this setting is used for parts considered unimportant to the calculation of availability (for example, vendor managed parts or floor stock items). • **Normal**—Available dates for supplies and demands of the part are calculated using all applicable capable-to-promise rules and settings. **Default value:** FromType	String (Enum)	
Value	A unique string identifier for this control setting.	String	Yes
Parts	Set of **Part** records that reference this **AvailableRule** value.	Set	

BOMType table

The **BOMType** table is a control table that specifies the different types of bill records and the processing rules for them. The **BOMType.Value** is a text string assigned to each parent-child record in the BillOfMaterial table. Each **BOMType.Value** defined represents a set of configuration rules that control the behavior for that parent-child relationship.

Table 7.9: BOMType (Mfg) fields

Field name	Description	Data type	Key
BlowThrough	Specifies whether to use phantom BOM relationships or "Blow Through" bill logic. Dependent demand generated through this Bill record bypasses the netting of the component. Valid values are: • Y • N **Default value**: N **Note:** This setting is ignored (always treated as "N") on BOMType records used to define co-product or by-product configurations.	Boolean	
ControlSet	The control set associated with this BOMType record. **Referenced table:** ControlSet	Reference	Yes

Table 7.9: BOMType (Mfg) fields

Field name	Description	Data type	Key
DateRule	When determining bill date effectivity, this field specifies which date to test for. Valid values are: • **AnchorDate**—the supply record's anchor date (**ScheduledReceipt.AnchorDate**) is used to determine which components of the BillOfMaterial are effective for explosion purposes. • **BlowThroughCalcDueDate**— BillOfMaterial effectivity is determined using either the ScheduledReceipt.ReschedDate or PlannedOrder.DueDate of the real assembly. Unless the assembly is a phantom, this option is identical to CalcDueDate. • **CalcDueDate**—the **FirstEffectiveDate** and **LastEffectiveDate** values on the BillOfMaterial record are compared using the **ScheduledReceipt.ReschedDate** or **PlannedOrder.DueDate** to determine which BillOfMaterial records will have dependent demand generated on them. • **CalcDockDate**—a supply order's dependent demands are based on the components that are effective at the supply order's calculated dock date. That is, the **FirstEffectiveDate** and **LastEffectiveDate** values on the BillOfMaterial records are compared using either **ScheduledReceipt.ReschedDockDate** or **PlannedOrder.DockDate**. • **CalcStartDate**—the supply record's calculated start date (**ScheduledReceipt.CalcStartDate**) is used to determine which components of the BillOfMaterial are effective for explosion purposes. • **Ignore**—the supply record ignores the **BillOfMaterial.EffectiveInDate** and **BillOfMaterial.EffectiveOutDate** resulting in the component always being considered for explosion. **Default value:** Ignore	String (Enum)	
DependentDemand Model	Specifies the model to use when the parent model should not be used in order BOMs. When set to null, the model of the dependent demand is identical to the model of the parent. When this field is set to a model name, the referenced model is the model of the dependent demand. **Referenced table:** Model **Note:** This field was added in Version 2016.2.	Reference	

Table 7.9: BOMType (Mfg) fields

Field name	Description	Data type	Key
DependentUnit Rule	Specifies how dependent demands are handled with unit effectivity. If your company has not enabled Model-Unit Effectivity, this field is ignored. Valid values are: • **Split**—split dependent demand according to the unit number range. Demands are not split if the supply's unit is less than zero. • **First**—calculate the entire dependent demand according to StartUnit on the supply record. Do not split the order according to unit effectivity. **Default value**: Split **Note:** This setting is ignored on BOMType records that define co-product or by-product configuration.	String (Enum)	
Description	A text description of the BOMType.Value. **Default value**: blank string	String	
EffectivityRule	Specifies for each BOMType how ranges of units and dates are interpreted when determining effectivity. This field applies to all effectivity rules (ranges apply to dates and unit ranges). Valid values are: • **InclusiveExclusive**—the record is effective starting on start and ending before the end (recommended method). • **Never**—the record is ignored regardless of all dates and Model and Unit Effectivity rules. • **Always**—ignore all other effectivity rules and treat Bill as active. • **Exclusive**—use effectivity dates and units if applicable (not effective on the dates or units). • **Inclusive**—effective from start to end inclusive. **Default value**: InclusiveExclusive	String (Enum)	
ExplodeNegatives	Specifies how negative quantities per each of the BOMTypes are handled. Valid values are: • **Y**—negative QuantityPer is used in the explosion calculation. • **N**—negative QuantityPer is not used in the explosion calculation. **Default value:** N **Note:** This setting is ignored on BOMType records that define a co-product or by-product configuration (always treated as "Y" since QuantityPer values are required to be negative on all BillOfMaterial records that define co-products or by-products).	Boolean	

Table 7.9: BOMType (Mfg) fields

Field name	Description	Data type	Key
IgnoreAssembly Yield	Controls whether or not an assembly's yield is ignored from one component to another when calculating dependent demand quantities (that is, is the dependent demand quantity inflated for the assembly's yield or not). Valid values are: • **Y**—the component from the BOM record ignores the assembly's yield when calculating the dependent demand quantity (the quantity is not inflated in consideration of the assembly's yield). For example, if an assembly containing expensive components needs to be scrapped due to issues with another component, it might be desirable for the expensive components to be recovered from the assembly before scrapping it. • **N**—the component from the BOM record considers the assembly's yield when calculating the dependent demand quantity (the quantity is inflated in consideration of the assembly's yield). **Default value**: N **Note:** This setting is ignored on BOMType records that define a co-product or by-product configuration (always treated as "Y").	Boolean	
LimitEffective Date	Specifies for each **BOMType.Value** where an assembly has a past due demand whether effectivity of components is determined using the current DueDate (considering that it is prior to the **Assembly.RunDate**) or the RunDate itself. • **Y**—the **Assembly.RunDate** is used. This ensures that any past due demand uses BillOfMaterial records currently in effect (as of the RunDate). This setting overrides the explosion date (StartDate of the peg supply). As a result, bills not effective at RunDate are ignored (supply does not explode through them). • **N**—the **DueDate** is used. This ensures that the BillOfMaterial configuration at the time of the DueDate will be used. **Default value**: N	Boolean	

Table 7.9: BOMType (Mfg) fields

Field name	Description	Data type	Key
MPSConfig DemandSource	Specifies which components on the BillOfMaterial table are considered when looking for component actual sales to consume assembly forecast within a PlanningBOM relationship. Four conditions must be met for this to occur: • Assembly part has **PartType.ProcessingRule** set to 'MPSConfig' • The BillOfMaterial record defining the relationship between Assemblies and Components must have a **BOMType.MPSConfigDemandSource**='Y'. • The Component has independent demand records where **DemandType.ProcessingRule**='SalesActual' • The Assembly has independent demand records where **DemandType.ProcessingRule** = 'SalesForecast' or 'ProductionForecast'. Valid values are: • **Y**—this BOMType uses component consumption of assembly forecast within a PlanningBOM. • **N**—this BOMType does not use component consumption of assembly forecast within a PlanningBOM. **Default value**: N **Note:** This setting is ignored on all BOMType records that define a co-product or by-product configuration.	Boolean	
MUERule	Specifies how model and unit effectivity are to be applied. MUERule is used regardless of whether the parent or component parts are netted by model or unit. If Model-Unit Effectivity is not enabled then MUERule is treated as Ignore. Valid values are: • **Model**—the Bill record is effective if the Model value on the Bill record matches the **ScheduledReceipt.InputModel** or the model on the planned order. • **Unit**—the Bill record is effective if the StartUnit on the Supply record is in the range of the StartUnit and EndUnit from the Bill record. DependentUnitRule and EffectivityRule are tested to determine whether the unit is in range. • **ModelUnit**—use both model and unit tests simultaneously. Model matches and the unit must be in range for the Bill record to be effective. • **Ignore**—do not test model or unit for this Bill record. **Default value**: Ignore	String (Enum)	

Table 7.9: BOMType (Mfg) fields

Field name	Description	Data type	Key
ProductType	Specifies the component's relationship to the assembly. This setting determines whether dependent requirements are passed to the component, as well as how certain values on the BOM record are interpreted. Valid values are: • **Normal**—a normal dependent component used in the production of the assembly. • **CoProduct**—a co-product that can be manufactured and planned together with the assembly (primary) product due to common structure, components and process similarities. For example, a co-product might be a lower grade version of the primary product. Netting and CTP calculations for parts with a co-product relationship are performed at the same time. Therefore, two-way co-product relationships are supported. • **ByProduct**—a by-product that is generated from, and residual to, the production of the assembly (primary) product. For example, a by-product might be a chemical generated from the production of one or more assemblies in a given product structure. Netting and CTP calculations for a by-product part are performed after all of its BillOfMaterial assemblies have been planned. Therefore, two-way by-product relationships are not supported. For more information about co-products or by-products, see "Co-products and by-products" on page 1581. **Default value:** Normal	String (Enum)	
RatioRule	Specifies how the BillOfMaterial.OptionRatio is used. Valid values are: • **Ignore**—do not use the OptionRatio field in explosion • **Fraction**—value from 0 through 1 (1 means used in all assemblies) • **Percent**—value from 0 through 100 (100 means used in all assemblies) **Default value:** Fraction	String (Enum)	

Table 7.9: BOMType (Mfg) fields

Field name	Description	Data type	Key
RoundingRule	Specifies for each BOMType the rules for rounding numbers when exploding supplies through the BOM to place dependent demands on components. Valid values are: • **None**—do not round. • **Up**—round up to next integer. • **Down**—round down to next integer. • **Nearest**—round to nearest integer (.5 goes up). • **QtyPerOrder**—ignores the supply quantity on the order and pass dependent demand equal to the **BillOfMaterial.QuantityPer** value. For example, if the supply quantity is 10 and QuantityPer is 2, then the dependent demand will be 2. **Default value:** None	String (Enum)	
ScrapRule	Specifies how to handle scrap and yield values on BOMType records. Valid values are: • **Ignore**—do not use the Scrap factor • **YieldFraction**—value from 0 through 1 (1 = no loss) • **YieldPercent**—value from 0 through 100 (100 =no loss) • **ScrapFraction**—value from 0 through 1 (0 = no loss) • **ScrapPercent**—value from 0 through 100 (0 = no loss) • **InflationFraction**—formula = 1 / (1 + **BillOfMaterial.Scrap**) • **InflationPercent**—formula = 1 / (1 + **BillOfMaterial.Scrap** * 0.01) **Default value**: YieldFraction	String (Enum)	
UseLeadTime Offset	Specifies for each BOMType whether to use a separate lead-time factor on BillOfMaterial records. Valid values are: • **Y**—the lead-time value that is provided is used in all lead-time calculations. Setting this value to Y enables the use of the BillOfMaterial.LeadTimeOffset field as a factor in addition to Part and PartSource based lead-time elements such as FixedLeadTime, VariableLeadTime, and SafetyLeadTime, in calculating product lead time and start dates. • **N**—the lead-time value that is provided is not used in all lead time calculations. **Default value**: N	Boolean	
Value	The string value for this type of bill. This value appears in the BillOfMaterial.Type field. **Default value**: blank string	String	Yes
BillOfMaterials	Set of **BillOfMaterial** records that reference this BOMType value.	Set	

Calendar table

Calendars are used for date calculations. Common calendars used in manufacturing include shop calendars (workdays), and month calendars (defines beginning of monthly reporting periods). Each calendar has a name defined in the **Calendar** table. The calendar is defined by a list of dates associated with the calendar name.

Table 7.10: Calendar (Core) fields

Field name	Description	Data type	Key
BucketingName	An alternative name for this calendar (such as, the name of a supplier's internal calendar). This field is not used by RapidResponse analytics. **Default value**: blank string	String	
Description	A description of the calendar and the periods it represents.	String	
PlanningOnly	Used to exclude a calendar from appearing in the dialog boxes in which users choose worksheet bucket settings. This can be useful in eliminating calendars a user is not expected to see or to simply present a more manageable set of calendars. Note that regardless of this setting, all calendars are available for planning purposes (for example, for use by a PlanningCalendar record). Valid values are: • **N**—Calendar is available for planning purposes and is also available for selection by users when applying worksheet bucketing. This setting corresponds to how calendars always worked in versions prior to 2016.2. • **Y**—Calendar is available for planning purposes only. It will not show or be selectable in dialog boxes by users when choosing how to bucket data in worksheets. **Default value:** N **Note:** This field was added in Version 2016.2, Service Update 4.3.	Boolean	
Value	The name of a Calendar. A valid calendar name must begin with an alphabetic character, and can then include alphabetic, numeric, and underscore characters. No special characters are allowed. **Default value**: blank string	String	Yes
FirstDate	The earliest CalendarDate.Value for the calendar. This is a calculated field.	Date	

Table 7.10: Calendar (Core) fields

Field name	Description	Data type	Key
LastDate	The latest CalendarDate.Value for the calendar. This is a calculated field.	Date	
AsOfDateCalendar SafetyStockItem Types	Set of **SafetyStockItemType** records that use this calendar to define an "as of date".	Set	
ConstraintCalendar	Set of **Constraint** records using this Calendar when allocating constraint to load.	Set	
ConstraintDataDate	Set of **Constraint** records using this Calendar to define the current constraint period.	Set	
CycleCalendar SafetyStockItem Types	Set of **SafetyStockItemType** records that use this calendar as their cycle calendar.	Set	
DRPHorizonCalendars	Set of **DRPHorizon** records that reference this Calendar. This includes only records that are using the global default setting from the **DRPConfiguration** table.	Set	
DRPPartSiteHorizonCalendars	Set of **DRPHorizon** records that have that reference this Calendar. This includes only records that are using the settings from the **PartSolution** table.	Set	
Dates	Set of **CalendarDate** records that reference this Calendar.	Set	
Forecast Disaggregation Parameters InnerCalendars	Set of **ForecastDisaggregationParameters** records that use this Calendar as the inner calendar for forecast disaggregation.	Set	
Forecast Disaggregation Parameters OuterCalendars	Set of **ForecastDisaggregationParameters** records that use this Calendar as the outer calendar for forecast disaggregation.	Set	
ForecastItem ParametersTypes	Set of **ForecastItemParametersType** records that use this Calendar when bucketing actuals and generating the statistical forecast.	Set	
HistoricalSupply Headers	Set of **HistoricalSupplyHeader** records that reference this calendar.	Set	

Table 7.10: Calendar (Core) fields

Field name	Description	Data type	Key
LeadTimeCalendar SafetyStockItem Types	Set of **SafetyStockItemType** records that use this calendar as their lead time calendar.	Set	
MPSCalendars	Set of **MPSConfiguration** records that use this calendar for bucketing purposes.	Set	
MPSRunDate Calendars	Set of **MPSConfiguration** records that use this calendar to define the current system date.	Set	
MPSTolerance Calendars	Set of **MPSConfiguration** records that use this calendar to define the current system date.	Set	
OrderPriorities	Set of **OrderPriority** records that use this calendar.	Set	
PartCustomers	Set of **PartCustomer** records that use this calendar.	Set	
PeriodCalendar SafetyStockItem Types	Set of **SafetyStockItemType** records that use this calendar as their period calendar.	Set	
PlanningCalendars AllocationCalendar	Set of **PlanningCalendars** records that use this Calendar when performing fair and equal-share allocations.	Set	
PlanningCalendars CoByProduct PlanningInterval	Set of **PlanningCalendars** records that use this Calendar for defining co-product and by-product planning intervals.	Set	
PlanningCalendars DataDate	Set of **PlanningCalendars** records that use this Calendar for identifying when data was last updated.	Set	
PlanningCalendars ExpiryCalendars	Set of **PlanningCalendars** records that use this Calendar for material expiry planning.	Set	
PlanningCalendars Forecast	Set of **PlanningCalendars** records that use this Calendar for defining forecast intervals.	Set	
PlanningCalendars OrderPoint Increases	Set of **PlanningCalendars** records that use this Calendar for defining intervals used when calculating if an increase in the "order point" threshold should be applied.	Set	

Table 7.10: Calendar (Core) fields

Field name	Description	Data type	Key
PlanningCalendars PercentSafety Interval	Set of **PlanningCalendars** records that use this Calendar for bucketing in PercentOfDemand and FractionOfDemand safety stock calculations.	Set	
PlanningCalendars PeriodSupplyDue	Set of **PlanningCalendars** records that use this Calendar when setting valid planned order due dates for "days of supply" parts.	Set	
PlanningCalendars PeriodSupply Interval	Set of **PlanningCalendars** records that use this Calendar when accumulating intervals of demands for "days of supply" parts.	Set	
PlanningCalendars RunDate	Set of **PlanningCalendars** records that reference this Calendar when determining the date that data was extracted from the enterprise data source.	Set	
PlanningCalendars SecondCalendar	Set of **PlanningCalendars** records that use this Calendar for MPS and MPSConfig parts with forecast spreading.	Set	
PlanningCalendars Substitution ToleranceCalendar	Set of **PlanningCalendars** records that use this Calendar for part substitution calculations.	Set	
PlanningCalendars TimeFence	Set of **PlanningCalendars** records that use this Calendar for determining dates on which the demand time fence will fall.	Set	
PlanningCalendars TimeUnits	Set of **PlanningCalendars** records that use this Calendar to determine valid working dates for "units of time" parameters.	Set	
PlanningCalendars Weekly	Set of **PlanningCalendars** records that use this Calendar for certain weekly reporting calculations in RapidResponse.	Set	
ProjectRunDate	Set of **Project** records that use this Calendar for defining their run date.	Set	
ProjectType Calendars	Set of **ProjectType** records that use this Calendar for defining the project calendar.	Set	
ProjectType PenaltyCalendars	Set of **ProjectType** records that use this Calendar for defining the project penalty calendar.	Set	

Table 7.10: Calendar (Core) fields

Field name	Description	Data type	Key
RangeOfCoverage Average Requirement Intervals	Set of **RangeOfCoverage** records that use this Calendar for setting the intervals over which average daily demands are calculated.	Set	
RangeOfCoverage Intervals	Set of **RangeOfCoverage** records that use this Calendar for determining range of coverage zones.	Set	
ResourceTypes	Set of **ResourceType** records that use this Calendar for defining the resource calendar.	Set	
SafetyStockItem Types	Set of **SafetyStockItemType** records that use this calendar.	Set	
SafetyStockPolicies	Set of **SafetyStockPolicy** records that use this calendar.	Set	
ShipCalendar Sources	Set of **Source** records that use this Calendar when determining ship dates.	Set	
SOPBaseCalendars	Set of **SOPAnalyticsConfiguration** records that use this Calendar as the disaggregation calendar for forecast disaggregation.	Set	
SOPCycleCalendars	Set of **SOPAnalyticsConfiguration** records that use this Calendar to define the S&OP cycle.	Set	
SOPInnerCalendars	Set of **SOPAnalyticsConfiguration** records that use this Calendar as the inner calendar for forecast disaggregation.	Set	
SOPOuter Calendars	Set of **SOPAnalyticsConfiguration** records that use this Calendar as the outer calendar for forecast disaggregation.	Set	
SOPRunDate Calendars	Set of **SOPAnalyticsConfiguration** records that use this Calendar to define the current system date.	Set	
SourceLeadTime Units	Set of **Source** records that use this Calendar when determining start dates.	Set	
TaskType Calendars	Set of **TaskType** records that use this Calendar for defining the task calendar.	Set	

Table 7.10: Calendar (Core) fields

Field name	Description	Data type	Key
TaskType PenaltyCalendars	Set of **TaskType** records that use this Calendar for defining the task penalty calendar.	Set	
ToleranceProfile Baseline	Set of **ToleranceProfile** records that use this Calendar when identifying the baseline historical demand or supply series.	Set	
ToleranceProfile Tolerance	Set of **ToleranceProfile** records that use this Calendar when evaluating level of change.	Set	

Note: All calendar names must begin with an alphabetic character.

CalendarDate table

The **CalendarDate** table contains a list of dates that can be used in calendar tables. The dates are loaded from data located in the enterprise data source.

Note that the earliest date allowed on a **CalendarDate** record is `01-02-1970` and earlier dates are always taken to mean "Past". Similarly, the latest date allowed on a **CalendarDate** record is `12-31-2037` and later dates are always taken to mean "Future".

Table 7.11: CalendarDate (Core) fields

Field name	Description	Data type	Key
Calendar	Reference to the calendar name. This field references the Calendar table. For information about this table, see "Calendar table" on page 695. **Referenced table:** Calendar	Reference	
DisplayValue	A label that can be displayed in worksheet buckets in place of a period's Value.	String	
Value	A date that defines the beginning of a period in the named calendar. **Default value**: Undefined	Date	

ConstraintType table

This table supports the Constraint Manager application, and defines rules that control how each constraint is processed.

Table 7.12: ConstraintType (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this ConstraintType record. **Referenced table:** ControlSet	Reference	Yes
Description	Additional information about this Type.	String	
EffectivityRule	Specifies how ConstraintAvailable effectivity dates are interpreted. Valid values are: • **InclusiveExclusive**—records are effective starting with Constraint period including In date and ending before the period containing Out date (this is the recommended method and the default). • **Always**—ignore effectivity dates and treat all ConstraintAvailable record as effective. • **Exclusive**—effective from the period after In to the period before Out. • **Inclusive**—effective from the period containing In to the period containing Out inclusive. • **Never**—no ConstraintAvailable records are effective. **Note:** Always only affects date effectivity, not CumulativeMax calculations.	String (Enum)	
FillSchedule	Controls whether netting tries to fill the constraint's schedule by planning to use constraint as early as possible, or if it only plans enough to satisfy demand dates. Valid values: • **Y**—Netting tries to fill constraint schedule to use constraint as early as possible. For "constrained" and "load only" constraints, Netting will pull orders earlier in to fill the constraint schedule and CTP will use the results for availability and constraint reporting. For "unconstrained" constraints, Netting does not try to fill in the constraint schedule , however if the **AvailableDateLimit** setting is "now", then CTP will schedule orders as early as possible with this setting. • **N**—Netting schedules constraint only to satisfy demand dates. This is the recommended value. Default: N If any constraint used by a part source is set to fill (Y), then all supplies using that part source will be planned to fill (regardless of whether their FillSchedule setting is Y or N). For more information, see "FillSchedule" on page 1665.	Boolean	

Table 7.12: ConstraintType (Mfg) fields

Field name	Description	Data type	Key
ProcessingRule	Specifies how a constraint is applied. Valid values are: • **Constrained**—CumulativeMax and ConstraintAvailable limits are applied. • **CumMax**—load is calculated as if the Constraint has unlimited availability in every period. CumulativeMax calculations are effective for both order planning and available date calculations. • **LoadOnly**—load is calculated as if the Constraint has unlimited availability in every period. CumulativeMax and period ConstraintAvailable are ignored. • **PlanningOnly**—the Constraint is considered (treated as "Constrained") during netting calculations so that part source selection is made based on constraint availability. However, the Constraint is ignored (treated as "LoadOnly") during CTP available date calculations. • **Unconstrained**—the Constraint is never effective and is ignored from processing. This acts as if the Constraint had unlimited availability and Load is not calculated. • **UnconstrainedPlan**—the Constraint is ignored (treated as 'Unconstrained') during netting calculations so supplies are planned when needed based on material requirements only. However, the Constraint is considered (treated as 'Constrained') during Capable-to-Promise calculations so available dates reflect what is possible once constraints are taken into account. **Default:** Unconstrained **Note:** For more information about the effect of the ProcessingRule setting, see "ProcessingRule" on page 1652.	String (Enum)	
ReportLimit	The number of days from DataDate to generate **PeriodConstraintLoad** records. This value should be expressed in terms of the standard Gregorian (everyday) calendar. Constraint loads are reported beyond that in the **ConstraintLoad** and **ConstraintSpreadLoad** table , but no additional **PeriodConstraintLoad** records are produced.	Integer	

Table 7.12: ConstraintType (Mfg) fields

Field name	Description	Data type	Key
SchedulingRule	Specifies how constraint scheduling is performed during Netting calculations. Constraints are always first scheduled in a "backward" phase during which constrained supplies are matched to or planned for demands. If pre-planning is enabled and there is insufficient constraint available, then earlier periods are looked to first for additional constraint. By default, a subsequent "forward" phase is then applied to optimize the initial ordering of supplies. This phase can improve scheduling by ensuring high priority supplies are pre-planned first and ensuring related supplies/products are built in continuous blocks to reduce changeover costs. This setting allows disabling the forward phase which can produce a better schedule under certain conditions (such as, when there are parallel constraints). Valid values are: • **BackloadOnly**—Only the backward phase of constraint scheduling is performed (forward phase is disabled). If pre-planning is required when using this setting, low priority supplies will be pre-planned first. It is intended for cases where part sources are constrained by multiple different constraints (particularly if used with partial planning logi), and where supplies should be planned as close to the due date as possible. This setting is also recommended if multi-level search logic is heavily used. • **Normal**— Both the backward and forward phases of constraint scheduling are performed. If pre-planning is required when using this setting, high priority supplies will be pre-planned first. It is recommended for cases where supplies should use constraint in continuous blocks (such as, if there are high changeover costs) or where it is important to pre-plan higher priority supply first. This setting corresponds to how constraint scheduling was always performed prior to Service Update 1906. **Default value**: Normal **Note**: This field was added in Service Update 1906. For more information, see "SchedulingRule" on page 1667.	String (Enum)	
Value	Name for a particular ConstraintType.	String	Yes
Constraints	Set of **Constraint** records that reference this Constraint value.	Set	

ConstraintUnitOfMeasure table

This table supports the Constraint Manager application, and contains the units of measure names used by constraints.

Table 7.13: ConstraintUnitOfMeasure (Mfg) fields

Field name	Description	Data Type	Key
Constraints	Set of **Constraint** records that reference this ConstraintUnitOfMeasure value.	Set	
ControlSet	The control set associated with this ConstraintUnitOfMeasure record. **Referenced table:** ControlSet	Reference	Yes
Description	Additional information about this ConstraintUOM.	String	
UnitOfMeasure	The unit of measure associated with this ConstraintUnitOfMeasure record. **Referenced table:** UnitOfMeasure **Note:** This field was added in Version 2016.2, Service Update 12.	Reference	
Value	A Unit of Measure that can be used by Constraints.	String	Yes

CRPUnitOfMeasure table

This table defines the different units of measurement used to interpret run times on an operation. It defines the calculation to convert the run time of an operation into standard hours of load.

Table 7.14: CRPUnitOfMeasure (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set that this CRPUnitOfMeasure record is associated with. **Referenced table:** ControlSet	Reference	Yes
CRPOperations	Set of **CRPOperation** records that reference this CRPUnitOfMeasure value.	Set	
Description	A description of this type of operation. An explanation of the code in the Value field. **Default value**: blank string	String	
Operations	Set of **Operation** records that reference this CRPUnitOfMeasure value.	Set	
ProcessingRule	• **UnitsPer Time** — uses the formula (1 / (RunTime * ScaleFactor) • **TimePerUnits** — uses the formula (RunTime * ScaleFactor)**Default value:** TimePerUnits	String (Enum)	

Table 7.14: CRPUnitOfMeasure (Mfg) fields

Field name	Description	Data type	Key
ScaleFactor	Specifies how to scale the value of the RunTime field on the Operation table. **Default value**: 1	Quantity	
UnitOfMeasure	The unit of measure that this CRPUnitOfMeasure record is associated with. **Referenced table:** UnitOfMeasure **Note**: This field was added in Version 2016.2, Service Update 9.	Reference	
Value	The string code for this type of operation. This value appears in the Operation records. **Default value**: blank string	String	Yes

DaysSupplyPolicy table

The **DaysSupplyPolicy** table contains settings that specify how demands should be accumulated and planned orders generated for parts that have days of supply logic enabled. Days of supply logic is meant to reduce the total number of planned orders generated by allowing a single planned order to satisfy all demands accumulated over a specified number of days or intervals. For example, all demands over each two-week period of demand might be satisfied by one planned order.

Each record in this table contains both short-term and long-term days of supply settings that apply to parts that reference it through the **Part.DaysSupplyPolicy** field. For example, demands might be accumulated weekly for the first two months in the horizon, and monthly after that. The **Fence** and **FenceCalendar** fields in this table are used to set the transition point between the short-term and long-term horizon for days of supply settings.

Note that for parts that only need one set of days of supply settings, then legacy days of supply settings as defined on the **Part, PartType**, and **PlanningCalendars** tables can be used instead. Alternatively for this case, the **DaysSupplyPolicy** table can still be used but with either the short-term horizon set large enough to cover the entire planning horizon, or with the short-term horizon set to "0" and the long-term horizon left to cover the entire planning horizon.

This table was added in Version 2016.2. For more information about days of supply logic, see "Days of Supply calculations" on page 1362.

Table 7.15: DaysSuppyPolicy (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set that this **DaysSupplyPolicy** record is associated with. **Referenced table:** ControlSet	Reference	Yes

Table 7.15: DaysSuppyPolicy (Mfg) fields

Field name	Description	Data type	Key
DaysSupplyRule	This setting determines how demands are accumulated and new orders generated within the short-term horizon for parts that use this days of supply policy. Valid values are: • **ByPeriod**—uses the values in **PeriodSupplyInterval** calendar, and over the number of intervals set by the **NumberOfDaysSupply** field (starting from the due date of the first unsatisfied demand). A single planned order to satisfy those demands is then generated on the first interval of the **PeriodSupplyDueCalendar** within the accumulation period. • **ByPeriodEnd**—demands are accumulated in intervals of the **PeriodSupplyInterval** calendar, and over the number of intervals set by the **NumberOfDaysSupply** field (starting from the due date of first unsatisfied demand). A single planned order is then generated on the last **PeriodSupplyDueCalendar** interval within the accumulation period. • **ByPeriodEndWithPriority**—demands of each priority level are accumulated separately in intervals of the **PeriodSupplyInterval** calendar, and over the number of intervals set by the **NumberOfDaysSupply** field (starting from the due date of first unsatisfied demand). For each group of prioritized demands, a single planned order is then generated on the last **PeriodSupplyDueCalendar** interval within the accumulation period. Note that the priority-based logic described above is only applicable to parts that have a **PartType.CommitLevel** setting of "High". For all other CommitLevel settings, this setting acts identically to the "ByPeriod" setting. • **ByPeriodWithPriority**—demands of each priority level are accumulated separately in intervals of the **PeriodSupplyInterval** calendar, and over the number of intervals set by the **NumberOfDaysSupply** field (starting from the due date of the first unsatisfied demand). For each group of prioritized demands, a single planned order is then generated on the first **PeriodSupplyDueCalendar** interval within the accumulation period. Note that the priority-based logic described above is only applicable to parts that have a **PartType.CommitLevel** setting of "High". For all other CommitLevel settings, this setting acts identically to the "ByPeriod" setting. • **FromDemand**—demands are accumulated in	String (Enum)	

Table 7.15: DaysSuppyPolicy (Mfg) fields

Field name	Description	Data type	Key
	Part.PlanningCalendars.TimeUnits calendar intervals, and over the number of intervals set by the **NumberOfDaysSupply** field (starting from the due date of the first unsatisfied demand). A single planned order is then generated on the due date of the first unsatisfied demand within the collection interval. • **FromSupply**—similar to the "FromDemand" setting except that demands accumulate starting from the due date when the supply can be planned (instead of the due date of the unsatisfied demand). In cases where there is a past-due demand for a part using this setting, the supply due date will be later than the demand due date, and hence the days supply horizon will end later. In typical cases where the supply due date and demand due date are the same, this field acts identically to "FromDemand". • **Ignore**—Days of supply planning is disabled for parts that use this policy. **Default value**: FromDemand		
Description	A description of this days of supply policy.	String	
Fence	The number of periods after RunDate where the fence between short-term and long-term days of supply horizons is placed (the actual date is reported in **Part.DaysSupplyFenceDate**). Before the fence date, short-term days of supply settings are used, while on or after the fence date, long-term days of supply settings are used. This should be expressed in **FenceCalendar** intervals. For example, if FenceCalendar is "Week" and this value is "12", then DaysSupplyFenceDate is calculated 12 weeks out from RunDate. The short-term settings apply up to that calculated fence date and the long-term settings apply on and after that through to the end of the planning horizon.	Integer	
FenceCalendar	A reference to the calendar in which the Fence value is expressed. For example, Week or Month. **Referenced table**: Calendar	Reference	

Table 7.15: DaysSuppyPolicy (Mfg) fields

Field name	Description	Data type	Key
LongTermDays SupplyRule	This setting determines how demands are accumulated and new orders generated within the long-term horizon for parts that use this days of supply policy. Valid values are: • **ByPeriod**—demands are accumulated in intervals of the **LongTermPeriodSupplyInterval** calendar, and over the number of intervals set by the **LongTermNumberOfDaysSupply** field (starting from the due date of the first unsatisfied demand). A single planned order to satisfy those demands is then generated on the first interval of the **LongTermPeriodSupplyDueCalendar** within the accumulation period. • **ByPeriodEnd**—demands are accumulated in **LongTermPeriodSupplyInterval** calendar intervals, and over the number of those intervals set by the **LongTermNumberOfDaysSupply** field (starting from the due date of the first unsatisfied demand). A single planned order is then generated on the last **LongTermPeriodSupplyDueCalendar** interval within the accumulation period. • **ByPeriodEndWithPriority**—demands of each priority level are accumulated separately in intervals of the **LongTermPeriodSupplyInterval** calendar, and over the number of intervals set by the **LongTermNumberOfDaysSupply** field (starting from the due date of first unsatisfied demand). For each group of prioritized demands, a single planned order is then generated on the last **LongTermPeriodSupplyDueCalendar** interval within the accumulation period. Note that the priority-based logic described above is only applicable to parts that have a **PartType.CommitLevel** setting of "High". For all other CommitLevel settings, this setting acts identically to the "ByPeriod" setting. • **ByPeriodWithPriority**—demands of each priority level are accumulated separately in **LongTermPeriodSupplyInterval** calendar intervals, and over the number of intervals set by the **LongTermNumberOfDaysSupply** field (starting from the due date of the first unsatisfied demand). For each group of prioritized demands, a single planned order is then generated on the first **LongTermPeriodSupplyDueCalendar** interval within the accumulation period. Note that the priority-based logic described above is only applicable to parts that have a **PartType.CommitLevel** setting of "High". For all other CommitLevel settings, this setting acts identically to the	String (Enum)	

Table 7.15: DaysSuppyPolicy (Mfg) fields

Field name	Description	Data type	Key
	"ByPeriod" setting. • **FromDemand**—demands are accumulated in **Part.PlanningCalendars.TimeUnits** calendar intervals, and over the number of specified **LongTermNumberOfDaysSupply** intervals (starting from the due date of the first unsatisfied demand). A single planned order is then generated on the due date of the first unsatisfied demand within the accumulation period. • **FromSupply**—similar to the "FromDemand" setting except that demands accumulate starting from the due date when the supply can be planned (instead of the due date of the unsatisfied demand). In cases where there is a past-due demand for a part using this setting, the supply due date will be later than the demand due date, and hence the days supply horizon will end later. In typical cases where the supply due date and demand due date are the same, this field acts identically to "FromDemand". • **Ignore**—Days of supply planning is disabled for parts that use this policy. **Default value**: FromDemand		
LongTermNumber OfDaysSupply	The number of days or intervals of demand that each planned order is intended to satisfy within the long-term days of supply horizon. The interpretation of this field is dependent on the **LongTermNumber Of DaysSupply** setting as follows: • If using the "FromDemand" or "FromSupply", rule, this field should be expressed in intervals of the part's **PlanningCalendars.TimeUnits** calendar. • If using the "ByPeriod", "ByPeriodWithPriority", "ByPeriodEnd" or "ByPeriodEndWithPriority" rule, this field should be expressed in intervals of the **LongTermPeriodSupplyInterval** calendar. **Note:** A value of "0" or less in this field is treated as if it were set to "1"; that is, supply is planned to satisfy one day/interval of demand.	Quantity	

Table 7.15: DaysSuppyPolicy (Mfg) fields

Field name	Description	Data type	Key
LongTermPeriod SupplyDateRule	When using any of the four "by period" days supply rules in the long-term planning horizon, this setting defines the dates that intervals in the **LongTermPeriodSupplyDueCalendar** and **LongTermPeriodSupplyIntervalCalendar** should align to. Valid values: • **DockDate**—long-term period calendars are aligned to dock dates. That is, demands are bucketed after consideration for dock-to-stock time and planned order dock dates must fall on intervals in the supply due calendar. This setting is useful for cases where dock-to-stock lead times vary between parts and their is a desire to co-ordinate the shipment of those parts at the sourcing site and subsequent receipt of those parts at the destination site. • **DueDate**—long-term period calendars are aligned to due dates. That is, demands are bucketed based on their due date and planned order due dates must fall on intervals in the supply due calendar. This setting corresponds to how days of supply calculations were always performed in versions prior to 2016.2. **Default value:** DueDate **Note:** This field was added in Version 2016.2, Service Update 4.3.	String (Enum)	
LongTermPeriod SupplyDueCalendar	Defines the calendar whose intervals define valid planned order due (or dock) dates within the long-term days of supply horizon. For example, if planned orders should only be due at the beginning of a week, then this might be set to a "Week" calendar. Or, if planned orders can be due on any working day, then this might be set to a "Weekly" calendar. Applicable only when **DaysSupplyRule** is set to "ByPeriod", "ByPeriodWithPriority", "ByPeriodEnd", or "ByPeriodEndWithPriority". **Referenced table**: Calendar	Reference	
LongTermPeriod SupplyInterval	Defines the calendar intervals over which demands are accumulated within the long-term days of supply horizon. For example, demands might be accumulated over weekly or monthly periods. Applicable when **LongTermDaysSupplyRule** is set to "ByPeriod", "ByPeriodWithPriority", "ByPeriodEnd", or "ByPeriodEndWithPriority". **Referenced table**: Calendar	Reference	

Table 7.15: DaysSuppyPolicy (Mfg) fields

Field name	Description	Data type	Key
NumberOfDays Supply	The number of days or intervals of demand that each planned order is intended to satisfy within the short-term days of supply horizon. The interpretation of this field is dependent on the **NumberOfDaysSupply** setting as follows: • If using the "FromDemand" or "FromSupply", rule, this field should be expressed in intervals of the part's **PlanningCalendars.TimeUnits** calendar. • If using the "ByPeriod", "ByPeriodWithPriority", "ByPeriodEnd" or "ByPeriodEndWithPriority" rule, this field should be expressed in intervals of the **LongTermPeriodSupplyInterval** calendar. **Note:** A value of "0" or less in this field is treated as if it were set to "1"; that is, supply is planned to satisfy one day/interval of demand.	Quantity	
PeriodSupplyDate Rule	When using any of the four "by period" days supply rules in the short-term horizon, this setting defines the dates that the **PeriodSupplyDueCalendar** and **PeriodSupplyIntervalCalendar** should align to. Valid values: • **DockDate**—short-term period calendars are aligned to dock dates. That is, demands are bucketed after consideration for dock-to-stock time and planned order dock dates must fall on intervals in the supply due calendar. This setting is useful for cases where dock-to-stock lead times vary between parts and their is a desire to co-ordinate the shipment of those parts at the sourcing site and subsequent receipt of those parts at the destination site. • **DueDate**—short-term period calendars are aligned to due dates. That is, demands are bucketed based on their due date and planned order due dates must fall on intervals in the supply due calendar. This setting corresponds to how days of supply calculations were always performed in versions prior to 2016.2. **Default value:** DueDate **Note:** This field was added in Version 2016.2, Service Update 4.3.		

Table 7.15: DaysSuppyPolicy (Mfg) fields

Field name	Description	Data type	Key
PeriodSupplyDue Calendar	Defines the calendar whose intervals define valid planned order due (or dock) dates within the short-term days of supply horizon. For example, if planned orders should only be due at the beginning of a week, then this might be set to a "Week" calendar. Or, if planned orders can be due on any working day, then this might be set to a "Weekly" calendar. Applicable only when **DaysSupplyRule** is set to "ByPeriod", "ByPeriodWithPriority", "ByPeriodEnd", or "ByPeriodEndWithPriority". **Referenced table**: Calendar	Reference	
PeriodSupply Interval	Defines the calendar intervals over which demands are accumulated within the short-term days of supply horizon. For example, demands might be accumulated over weekly or monthly periods. Applicable only when **DaysSupplyRule** is set to "ByPeriod", "ByPeriodWithPriority", "ByPeriodEnd", or "ByPeriodEndWithPriority". **Referenced table**: Calendar	Reference	
Value	A unique string value for this days of supply policy. This is referenced from the **DaysSupplyPolicy** field on the **Part** table.	String	Yes
Parts	Set of **Part** records that use this days of supply policy.	Set	

DemandStatus table

The **DemandStatus** table determines how demand is handled by RapidResponse analytics. For example, you can set **ProcessingRule** field to **Ignore** resulting in the demand being ignored by netting calculations.

Historical sales data (demand that has been shipped to a customer) can be defined by setting the **ProcessingRule** field in this table to **Ignore**. When loading historical sales data, it's recommended that the amount already shipped be loaded into the **IndependentDemand.ShippedQty** field. It's also recommended that you specify zero in the **IndependentDemand.Quantity** field.

Table 7.16: DemandStatus (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this DemandStatus record. **Referenced table:** ControlSet	Reference	Yes
Description	The description of the demand status.	String	

Table 7.16: DemandStatus (Mfg) fields

Field name	Description	Data type	Key
Forecast Consumption DateRule	Specifies the date from which the forecast consumption interval is determined for any independent demands with this status. Valid values are: • **DataDate**—Demand forecast consumption interval is set based on the later of **DueDate** or **Part.PlanningCalendars.DataDate** (this usually corresponds to today's date). As a result, on-time independent demands will consume forecast based on their **DueDate**, while past-due demands will consume forecast based on the **DataDate** (and typically consume more of the forecast than they would at their due date). • **DueDate—**Demand forecast consumption interval is set based on **DueDate**. This means that all independent demands with this status, whether on-time or late, will consume forecast based on their **DueDate**. • **FromPartType**—Demand forecast consumption interval is set based on a part's **PartType.ForecastConsumptionDateRule** setting. This setting only contains "DueDate" and "DataDate" options, and does not support using the **RequestDate** to determine forecast consumption. • **RequestDate**—Demand forecast consumption interval is set based on **RequestDate**. This means that all independent demands using this status will consume forecast based on their **RequestDate** regardless of when that request date is. • **RequestOrDataDate**—Demand forecast consumption interval is set based on the later of **RequestDate** or **Part.PlanningCalendars.DataDate** (this usually corresponds to today's date). With this setting, any demands where the **RequestDate** is in the past will consume forecast based on the **DataDate** (and typically consume more of the forecast than they would at their request date). **Default value:** FromPartType	String (Enum)	

Table 7.16: DemandStatus (Mfg) fields

Field name	Description	Data type	Key
Forecast Consumption Override	If a line item belongs to a demand order where the **DemandType.ProcessingRule** is set to "SalesActual", this setting controls whether that individual line item can consume forecast. Valid values are: • **DoNotConsume**—line items with this setting are not eligible to consume forecast demands. • **Normal**—line items with this setting can consume forecast demands according to the configured forecast consumption logic. **Default value**: Normal **Note:** For more information about forecast consumption, see "Forecast consumption" on page 1431.	String (Enum)	
ModelUsage	Indicates how the model associated with a given independent demand is determined. Actual usage of that model in analytic calculations is then set by the part's **MUEPoolNettingType.ModelRule** value. Valid values are: • **Ignore**—model is set to the default model; this is the first value loaded in the **Model** table and typically has a value of "None". The input value provided in **IndependentDemand.Model** is ignored. • **Normal**—model is set to the input value provided in **IndependentDemand.Model**. **Default value:** Normal	String (Enum)	
ProcessingRule	Specifies if the demand is used in RapidResponse netting calculations. Valid values are: • **Ignore**—demand is ignored by netting • **Current**—demand is used by netting (at least one DemandStatus value must use this setting) **Default value:** Current	String (Enum)	
Value	The string value for this type of DemandStatus.	String	Yes
Independent Demands	Set of **IndependentDemand** records that reference this DemandStatus value.	Set	

DemandType table

The **DemandType** table defines the values for types of demands. It is used in **IndependentDemand** table to identify the different types of demands and their processing rules. It is also used with other demand tables and control tables to specify demand-processing behavior.

At least one DemandType must be defined. Typically, there will be at least one DemandType for each of the following demands: customer or sales orders, forecast, shipments, and dependent demand.

Table 7.17: DemandType (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this DemandType record. **Referenced table:** ControlSet	Reference	Yes
AllotmentOrder	Specifies priority in which supply is allocated to demands that have the same due date. The priority is ascending, meaning the lower the value the higher the priority. For example, demands with an AllotmentOrder of 1 receive supply before demands with an AllotmentOrder of 10 given that they have the same due date. This value must be a positive integer. **Default value**: 0	Quantity	
Description	A description of this type of demand. **Default value**: blank string	String	
KindPriority	The OrderPriority extended applications can use for IndependentDemands when they do not want to "bump" existing commitments (for customer orders, should be lower than the priority of any customer orders, yet above forecast). This field is not used by RapidResponse calculations. **Referenced table:** OrderPriority (The Default = OrderPriority with the highest Number, which is the lowest priority).	Reference	

Table 7.17: DemandType (Mfg) fields

Field name	Description	Data type	Key
PlanningRule	Specifies how the Netting and Capable-to-Promise analytics handle any unsatisfied demand for a particular demand type within a given period (as defined by the ForecastCalendar referenced from each part's PlanningCalendars record). For example, when there is limited supply within a given period, it might be acceptable to ignore any unsatisfied forecasted demand, but any actual demand may still need to be fully satisfied. This field applies only to independent demands (forecast or actuals), consensus forecast, input allocations, and transfer dependent demands. Valid values are: • **Full**— the demand order is required to be fully satisfied. In cases of limited supply, the demand may look to future forecast intervals to find supply. Assuming the same Priority and DueDate, demands using this value are processed before demands set to 'Partial'. • **Partial**— the demand order can only consume supplies in the number of forward-looking forecast intervals specified in the **Part.UnsatisfiedDemandTolerance** field (the default value of "0" means the demand can only consume supplies inside the same forecast interval or earlier). In cases of limited supply, the demand therefore may be left partially, or not at all, satisfied. If using this rule, it is recommended to also have incremental availability calculations turned on (for example, to enable seeing the available date associated with the satisfied portion of an order). **Default value**: Full **Note:** For more information, see "Ignoring unsatisfied demands" on page 1420. **Note:** For any parts with a DaysSupplyRule value of "ByPeriod" or "ByPeriodWithPriority" the setting in this field is ignored (always treated as "Full").	String (Enum)	

Table 7.17: DemandType (Mfg) fields

Field name	Description	Data type	Key
ProcessingRule	This value determines how the demand is handled in MRP netting. Valid values are: • **FromPart**—dependent demands are processed for forecast consumption on a component by component basis. Dependent demand for each component is treated as either **SalesActual** (processed for forecast consumption) or **Regular** (not processed for forecast consumption) as determined by the component's setting in **PartType.DependentDemandForecastConsumption**. This value should not be used in DemandType records that are referenced by IndependentDemand records. If it is, then those IndependentDemand records will be treated as 'Regular' demands. • **Ignore**—ignore this demand entirely. • **SalesForecast**—this is forecast of expected independent demand of type SalesActual. It is consumed (reduced) by SalesActual. Just the unconsumed forecast on or after the Demand Time Fence (DTF) is used as demand in MRP netting. A sales demand consumes a sales forecast within the bounds of the Forecast intervals on the Part's planning calendar. • **SalesActual**—actual demand that was forecasted as SalesForecast. The**Quantity** field plus the **ShippedQty** field of the IndependentDemand record is used to consume sales forecast; however, only the Quantity field is the actual demand used in MRP netting. At least one of the defined DemandTypes must have a ProcessingRule set to SalesActual. • **ProductionForecast**—forecast for production usually generated by explosion through a planning bill. It is not consumed by any actual demand, and thus the entire quantity is used by netting (for all part types). Also, demand time fence does not affect ProductionForecast. It is not considered committed (actual) demand and therefore supply created to satisfy ProductionForecast demand results in ATP for MPS parts. • **Regular**—demand used in MRP netting that does not consume forecast. It is real demand and reduces the ATP (consumes supply). **Note:** DemandType.ProcessingRule does not impact ConsensusForecast.	String (Enum)	

Table 7.17: DemandType (Mfg) fields

Field name	Description	Data type	Key
SafetyLeadTime Rule	Determines whether the **SafetyLeadTime** values specified on the **Part** and/or **PartSource** tables can be applied to demands of this type. Safety lead time is used to account for fluctuations in supply and demand and impacts planned order due dates for parts having **PartType.UseSafetyLeadTime** set to either "Y" or "Soft". Note also that this setting is only applicable to dependent demands for parts having **PartType. DependentDemandSafetyLeadTimeRule** set to "FromDemand", and consensus forecast and independent demands for parts having **PartType IndependentDemandSafetyLeadTimeRule** set to "FromDemand". Valid values are: • **Use**—Safety lead time is used for demands of this type. • **Ignore**—Safety lead time is ignored for demands of this type. **Default value:** Use	String (Enum)	

Table 7.17: DemandType (Mfg) fields

Field name	Description	Data type	Key
SafetyStockDemandUsage	Indicates whether demands of this type should be included in dynamic safety stock calculations and hence whether they impact dynamically calculated safety stock levels. For example, irregular types of demand or some types of transfer demands might need to be excluded from use in dynamic safety stock calculations. . This setting applies to demands for parts that use any of the following **SafetyStockQuantityRule** options: • FractionOfDemand • PercentOfDemand • RangeOfCoverage • RangeOfCoverageLeadTime • TimePhasedRangeOfCoverage • TimePhasedSafetyDaysMaximum • TimePhasedSafetyDaysTotal Valid values are: • **Use**—demands of this type are included in dynamic safety stock calculations (will impact calculated safety stock levels). • **Ignore**—demands of this type are excluded from dynamic safety stock calculations (will not impact calculated safety stock levels). **Default value:** Use **Note:** This field was added in Version 2016.2, Service Update 14. Prior to this there was no way to exclude specific demand types from being used in safety stock logic. **Note:** For dependent demands on parts that use either of the "TimePhasedSafetyDaysMaximum" or "TimePhasedSafetyDaysTotal" settings, this field along with **SafetyStockPolicy.SafetyDaysDependentDemandUsage** determines whether a given demand is used in safety stock logic. That is, in order for the demand to be used, the part must reference a **SafetyDaysDependentDemandUsage** setting other than "None" and the dependent demand must resolve to a value of "Use" in this field.		
SpreadProfile	The profile to use if SpreadRule = **Spread**. A default profile is often defined with no elements for non-forecast demands. **Referenced table:** SpreadProfile.Value	Reference	

Table 7.17: DemandType (Mfg) fields

Field name	Description	Data type	Key
SpreadRule	Specifies whether spreading is applied to forecasted demands. Spreading only applies if ProcessingRule is **SalesForecast**. Valid values are: • **None**—do not use spread. • **Spread**—spread the forecast using values in the SpreadProfile table. **Default value:** None	String (Enum)	
Value	The string value for this type of demand. This value appears in the **DemandOrder.Type** field. **Default value**: blank string	String	Yes
DemandOrders	Set of **DemandOrder** records that reference this DemandType value.	Set	
PartCustomerTypes	Set of **PartCustomer** records that reference this DemandType value.	Set	
SupplyTypes	Set of **SupplyType** records that reference this DemandType value.	Set	

DDMRPRule table

The **DDMRPRule** table contains DDMRP related configuration settings. It is used to identify the demand-processing behavior settings used to turn DDMRP calculations on or off for parts using this rule. This table supports the DDMRP application. This control table turns on Decoupled Lead Time calculations for each part.

This table was added in Version 2016.2, Service Update 27.

Table 7.18: DDMRPRule (Mfg) fields

Field name	Description	Data type	Key
Description	A description of this type ProcessingRule.	String	
ProcessingRule	Specifies the processing rule for DDMRP calculations. This field can have one of two values. Valid values are: **Ignore** -the DDMRP calculations are ignored and not calculated. **DDMRP** -the DDMRP calculations are calculated for parts choosing this rule. **Default value:** Ignore	String (Enum)	
Value	The unique value specified for each record.	String	Yes

DistributionPlanningRule table

The **DistributionPlanningRule** table is referenced by the **Part** table and determines if **TimePhasedMaximumInventory** records for the part are used in CTP calculations to trigger pushing of supply from the source site to the destination site(s).

If a part at the sourcing site has the **DistributionPlanningRule.ProcessingRule** set to **Enable** and it exceeds the set maximum inventory level, this triggers a request for supply of the finished goods to be pushed (transferred) to the destination sites earlier than it is required there. Details of these pushed supply activities are reported in the **SupplyDemand.PushDate** field as well in **CTPActivity** records with a **Type** value of "PushTransferOut".

Note that the **TimePhasedMaximumInventory.Quantity** value sets the maximum inventory level to be held for a part at a souring site, and inventory above that level is then eligible to be pushed to the destination site. However there must be corresponding amounts of future demand at those sites for it to be allocated against (otherwise, inventory above the maximum might be held).

This table was added in Version 2016.2. For more information about how the settings in this table affect the transfer or pushing of supply, see "Distribution planning" on page 1717.

Table 7.19: DistributionPlanningRule fields

Field name	Description	Data type	Key

AllotmentRule	Indicates the type of fair share distribution allotment that is used for this part. Valid values are:
	• **Normal**—This uses a simple fair share allotment in the CTP calculation. If lateness occurs, priority becomes effective.
	• **ForwardBucketedFairShare**—This uses an enhanced fair share distribution allotment in the CTP calculations. The goal is to do the following:
	  • Start by satisfying the stock-outs at destination sites
	  • Once stock-outs are satisfied, bring destination sites up to their safety stock levels
	Allotments are performed in a planning cycle. The shortages that occur during one planning cycle are carried over into the following planning cycle.
		String(Enum)	

ControlSet	The control set associated with this **DistributionPlanningRule** record. **Referenced table**: ControlSet	Reference	Yes
Description	An optional description of this distribution planning rule. **Note:** This field was added in Version 2016.2, Service Update 27.	String	
Parts	Set of **Part** records that reference these **DistributionPlanningRules** values.	Set	

Table 7.19: DistributionPlanningRule fields

Field name	Description	Data type	Key
ProcessingRule	Indicates if the **TimePhasedMaximumInventory** record applicable to a given part is used to trigger the pushing of supply from source sites to destination sites before the supply is needed for demand at the destination. Valid values are: • **Disable**—The **TimePhasedMaximumInventory.Quantity** is not used in for the part. Thus, supply will not be pushed to destination sites before it is needed. • **Enable**—The **TimePhasedMaximumInventory**.**Quantity** is used for this part. If a part exceeds the set maximum inventory level at the sourcing site, this trigger requests for supply to be transferred (pushed) to the destination site(s) earlier than it is needed there. Note that these pushed supplies will respect the multiple quantity of the parent part source at the destination sites. When this setting is selected, the **AllotmentRule** setting further determines the type of fair share distribution allotment used and the **SupplyPushRule** setting can be used to generate push activities for all supplies instead of only early supplies. **Default value**: Disable	String(Enum)	

Table 7.19: DistributionPlanningRule fields

Field name	Description	Data type	Key
SupplyPushRule	Determines whether pushed supply activities are only generated for supplies that are early to satisfy demand at the destination site, or if they can also potentially be generated for all supplies (including those are at late to satisfy demand at the destination site). Valid values are: • **All**—Pushed supply actions are always generated when trasferring supply from the source site to the destination site. For supplies that are early to satisfy demand at the destination site, pushed supply actions are generated when the maximum inventory level is exceeded at the source site (identical to the "Early" setting). However, pushed supply actions are also generated in cases where supply is transferred either on time or late to satisfy demand at the destination site. With this setting, if supply is late to satisfy demand at the destination site, then pushed supply activities are still generated (the **SupplyDemand.PushDate** is populated and a **CTPActivity** record with **Type** set to "PushTransferOut" is generated). Additionally, dates on these pushed supplies are aligned as necessary to ensure the supply quantity being transferred to the destination site respects the parent part source's **MultipleQty**. • **Early**—When the maximum inventory level is exceeded at the source site, supply that is early to satisfy demand at the destination site is pushed to that site and only such early supply will generate pushed supply activities. This corresponds to how push-planning logic was always performed prior to Version 2016.2, Service Update 25. With this setting, if supply is late to satisfy demand at the destination site, then it is still "pulled" to that site but no pushed supply activities are generated. For example, the **SupplyDemand.PushDate** is not populated and there isn't a **CTPActivity** record with **Type** set to "PushTransferOut". Additionally, the supply quantities being transferred to the destination site might not align to the parent part source's **MultipleQty**. **Default value**: Early **Note**: This field was added in Version 2016.2, Service Update 25.	String (Enum)	
Value	A unique value used to identify the **DistributionPlanningRule** record.	String	Yes

DRPConfiguration table

The **DRPConfiguration** table contains settings that support the Distribution Requirements Planning (DRP) application in RapidResponse. This table contains exactly one record, and can be modified on a

scenario-by-scenario basis to model various planning scenarios.

The settings in the **DRPConfiguration** table are used in various DRP resources, such as the **Distribution Requirements Planning** workbook, but do not impact any analytic calculations. Note also that the settings in this table act as global defaults, some of which can be overridden at the part level using corresponding fields in the **PartSolution** table.

This table was added in the Version 2016.2, Service Update 5, to support the **Distribution Requirements Planning** application.

Table 7.20: DRPConfiguration (Solutions) fields

Field name	Description	Data type	Key
Calendar	A reference to the **Calendar** whose intervals define bucket sizes in the DRP application. For example, this might by a **Weekly** calendar. **Referenced table**: Calendar	Reference	
DRPFrozenWindow	Indicates the length of the **DRP Frozen Window** in **Calendar** intervals. The frozen window is then defined starting from **CalcStartDate** and ending after the number of intervals specified here. This window represents a near-term portion of the planning horizon within which changes to orders should be prevented or limited. This field value acts as a global default for all parts where **PartSolution**. **DRPFrozenWindow** is set to **-1**. Otherwise, if a non-negative value is provided in the **DRPFrozenWindow** field then it is used for the part. The part's effective **DRP frozen window**, from either the **PartSolution** or **DRPConfiguration** tables, is then reported in **PartSolution.EffectiveDRPFrozenWindow**.	Integer	
DRPHorizon	Indicates the length of the **DRP horizon** in **Calendar** intervals. The **DRP horizon** is then defined starting from **CalcStartDate** and ending after the number of intervals specified here. Within this horizon, the distribution requirements planner is actively executing the distribution requirements plan, such as aligning orders to demand and firming planned orders. This field value acts as a global default for all parts where **PartSolution.DRPHorizon** is set to **-1**. Otherwise, if a non-negative value is provided in the **DRPHorizon** field then it is used for the part. The part's effective **DRP Horizon**, from either the **PartSolution** or **DRPConfiguration** tables, is reported in **PartSolution.EffectiveDRPHorizon**.	Integer	
NewTransferType	A default transfer type that will be used for DRP inventory transfers. A reference to the **InventoryTransferType** table used to indicate the transfer type. **Referenced table**: InventoryTransferType	Reference	

Table 7.20: DRPConfiguration (Solutions) fields

Field name	Description	Data type	Key
PlanningHorizon	Indicates the length of the planning horizon in **Calendar** intervals. The planning horizon is then defined starting from **CalcStartDate** and ending after the number of intervals specified here. The planning horizon specifies the length of time that extends into the future for long-term planning. This field value acts as a global default for all parts where **PartSolution.DRPPlanningHorizon** is set to **-1**. Otherwise, if a non-negative value is provided in the **DRPPlanningHorizon** field then it is used for the part. The part's effective planning horizon, from either the **PartSolution** or **DRPConfiguration** tables, is reported in **PartSolution.EffectiveDRPPlanningHorizon**.	Integer	
SRIntransitStatus	A reference to the **SupplyStatus** table used to indicate the in-transit status of a DRP scheduled receipt. **Referenced table**: SupplyStatus	Reference	

ExpiryType table

The **ExpiryType** table contains rules controlling how lower-level component supplies are rolled up and used in calculating the expiry date on assemblies that reference a **PartType.ExpiryRule** setting of "DependentStart". Specifically, this table allows for designating components as "limiting components". A limiting component typically refers to a bottom-level component whose calculated available date should limit the expiry date on the higher-level assemblies where it is ultimately used (dependent on the assembly's **ExpiryRule** setting).

Note also that the settings in this table are always used in determining the **ExpiryStartDate** that is calculated on supplies for all parts that reference an **ExpiryRule** setting other than "Ignore" (the **ExpiryStartDate** is primarily used for calculating the expiry date on assemblies having an **ExpiryRule** setting of "DependentStart")

Table 7.21: ExpiryType (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set that this **ExpiryType** record belongs to. **Referenced table:** ControlSet	Reference	Yes
Description	An optional description of this expiry type. **Note:** This field was added in Version 2016.2, Service Update 27.	String	

Table 7.21: ExpiryType (Mfg) fields

Field name	Description	Data type	Key
ProcessingRule	Specifies whether the part is a limiting component or a normal component, and hence how the **ExpiryStartDate** is calculated for its supplies. The **ExpiryStartDate** calculated on component supplies is then rolled up the structure and subsequently impacts expiry calculations when used in assemblies having a **PartType.ExpiryRule** of "DependentStart". Typically, such assemblies should contain one or more limiting components. Valid values are: • **LimitingComponent**—If the part is a bottom-level component, then the **ExpiryStartDate** on its supplies is set to the date their expiry begins. By default, expiry begins on the available date but this is configurable using the **PartSourceType.ExpiryDateRule** setting. Additionally, input expiry start dates can be provided for on hand inventory and scheduled receipts. • **Normal**—If the part is a bottom-level component, then the **ExpiryStartDate** on its supplies is set to "Future". For "DependentStart" assemblies, the **ExpiryDate** on planned supplies is calculated by adding **PartSource.CTPIntervalsToExpiry** to the earliest **ExpiryStartDate** values rolled up from all component supplies. Note however that if the earliest **ExpiryStartDate** is "Future", then the assmebly supply's **AvailableDate** is used in the calculation instead. **Default value:** Normal Note: This field's usage was modified in Version 2016.2 (Service Update 6). For more information about how this field is used in **ExpiryStartDate** calculations, see "DependentStart" on page 1619.	String (Enum)	
Value	A unique string identifier for this record.	Quantity	
Parts	Set of **Part** records that reference this **ExpiryType** value.	Set	

ForecastItemParametersType table

This table is referenced by the **ForecastItemParameters** table. It contains the parameters used in calculating statistical forecasts for a given forecast item. For example, the statistical model and bucketing intervals used when calculating a statistical forecast are identified in this table.

Table 7.22: ForecastItemParametersType (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this ForecastItemParametersType record. **Referenced table:** ControlSet	Reference	Yes
CrostonsPredictRule	The value that determines if Croston's statistical forecasting method should report constant or sporadic predictions of future demand. Valid values are: • **Constant**—Croston's method should report constant predictions, or forecast values that are spread over all time periods. • **Sporadic**—Croston's method should report sporadic predictions, or forecast values that appear only at calculated intervals. **Default value**: Constant **Note:** When using the Croston's method, you can verify individual values for the final estimated non-zero demand at every InterarrivalValue and the final estimated arrival time using the **StatisticalForecastFitOutput** table. In the **ValueName** field, the **SmoothedValue** model output reports the final estimated non-zero demand at every InterarrivalValue and the **InterarrivalValue** model output reports the final estimated arrival time.	String (Enum)	
Description	A description of this ForecastItemParametersType record.	String	
DisaggregationActualsCategoryRule	The value that determines which historical demand category is used for statistical forecast disaggregation. Valid values are: • **Default**—The default historical demand category, as defined by the **SOPAnalyticsConfiguration** table, should be used for forecast disaggregation. • **UseOwn**—The historical demand category defined for the forecast item should be used for disaggregation. **Default value**: Default	String (Enum)	

Table 7.22: ForecastItemParametersType (Mfg) fields

Field name	Description	Data type	Key
FitMeasure	When "BestFit" is selected as the ForecastModel, this field indicates the measure used in selecting the statistical model that best fits the data. Valid values are: • **AdjustedRSquared**—Calculates the ratio between the regression sum of squares and total sum of squares measures similar to the RSquared measure, but is influenced by the number of values in the input data set. • **LagPercentageError**—Calculates the sum of differences between the simulated forecast and actuals in the first interval of the holdout period (after any offset), expressed as a percentage of all actuals in that interval. Applicable only when best fit is used with a holdout period. • **MeanAbsoluteError**—Determines the absolute value of the variance between the historical actual values and the predicted forecast values. • **MeanAbsoluteErrorByMean**—Normalizes the value returned by the mean absolute error measure by dividing it by the mean quantity of the input data. • **MeanAbsolutePercentageError**—Determines the absolute value of the variance between the historical actual values and the predicted forecast values with respect to the actual values, expressed as a percentage. • **MeanAbsoluteScaledError**—(non-seasonal) Determines the difference between the forecast error for a given period, which represents the actual value minus the forecast value for the same period, and then divides it by the mean absolute error of the one-step ahead naïve forecast. • **MeanError**—Determines the average variance between the historical actual values and the predicted forecast values. • **MeanPercentageError**—Determines the average variance between the historical actual values and the predicted forecast values with respect to the actual values, expressed as a percentage. • **MeanSquareError**—Calculates the average of the residual sum of squares for the forecast. • **RegressionSumSquares**—Determines the difference between the total sum of squares of the input data and the residual sum of squares, and shows how the variance of the statistical forecast and input values differs from the variance of the input values and average of input values. • **ResidualSumSquares**—Calculates the sum of the square of differences between the historical actual values and the values predicted by the statistical forecast. • **RollingLagPercentageError**— Calculates the sum of differences between the simulated forecast and actuals in a specified number	String (Enum)	

Table 7.22: ForecastItemParametersType (Mfg) fields

Field name	Description	Data type	Key
	of intervals of the holdout period, and then expresses this as a percentage of all actuals in those intervals. The number of intervals to use with this measure is set by the RollingErrorIntervalCount field on the ForecastItemParameters table, and is applied from the start of the holdout region (after any offset). This setting is applicable only when best fit is used with a holdout period. • **RootMeanSquareError**—Determines the square root of the value produced by the mean square errors measure, and shows the correlation between the historical actual values and the results of the statistical forecast calculation. • **RSquared**—Determines the ratio between the regression sum of squares and total sum of squares measures, and shows how closely the forecast values fit the historical actual values. • **SymmetricMeanAbsolutePercentageError**—Determines the absolute difference between the forecast values and historical actual values and divides it by half the sum of the forecast values and actual values, expressed as a percentage. The sMAPE error rate is limited to 200%. **Note:** This field was modified in Version 2016.2, Service Update 10 and 13.		

Table 7.22: ForecastItemParametersType (Mfg) fields

Field name	Description	Data type	Key
ForecastModel	Indicates the statistical model that will be used to calculate the statistical forecast.Valid values are: • **AdditiveHoltWintersMethod**—Differs from the Holt-Winters model in that forecast points are calculated in an additive, rather than multiplicative, manner. Suitable for demand that has constant variation over a period. For a more detailed description, see "Holt-Winters multiplicative and additive" on page 2037. • **ARIMA**—Calculates forecasts for a time period using a linear combination of actual values and error values in a time series. This model can be used on a stationary time series, or a differencing function can be applied to non-stationary data to make it stationary. For a more detailed description, see "Auto-Regressive Integrated Moving Average (ARIMA)" on page 2034. • **ARIMAX**—Is an extension of the ARIMA model, but also includes independent variables (regressors) in the forecast calculation. This makes ARIMAX a multiple linear regression model. To improve forecast accuracy, ARIMAX also takes into consideration autocorrelation that may be found in regressor residuals. For a more detailed description, see "ARIMAX" on page 2042. • **BestFit**—Fits each of the other forecast models and selects the one with the least margin of error. If the forecast item parameters reference a valid **BestFitProfile** record, then just the subset of models defined by the profile is used in the best fit process. Otherwise, if that **BestFitProfile** reference is Null, then all models (excepting "Rforecast") are used in the best fit process. For a more detailed description, see "Best fit" on page 2053. • **CrostonsMethod**— Uses exponential smoothing with a single smoothing constant for the forecast values, but calculates two different values; the first being the forecast values at a point and the second being the average length of time between forecasts. These values determine the forecast quantities and the periods that have forecast demands. Suitable for demand that is not constant, such as lumpy demand that contains periods of zero quantities. For a more detailed description, see "Croston's method" on page 2034. • **DoubleExponentialSmoothing**—Considers the data points and trends within the historical data, and applies a smoothing algorithm to both. The result is then used as the statistical forecast. Suitable for demand that is fairly stable but trending up or down over time. For a more detailed description, see "Double exponential smoothing" on page 2036. • **ElasticNet**—A multiple linear regression model that uses regularized, also known as penalized, regression methods. It blends Lasso and ridge regression techniques by penalizing both L1 and L2 norms to reduce the coefficient vector. To use ElasticNet, you must attach a minimum of two regressors to a forecast item or you won't be able to generate a statistical forecast. For a more detailed description, see "ElasticNet" on page	String (Enum)	

Table 7.22: ForecastItemParametersType (Mfg) fields

Field name	Description	Data type	Key
	2043. • **ExponentialSmoothing**— Considers data points within the historical data, and applies a smoothing algorithm. The result of the final data point is then used as a constant value for the statistical forecast. Suitable for demand that is fairly stable and lacks a trend. For a more detailed description, see "Exponential smoothing" on page 2037. • **ForecastImport**—The statistical forecast is set to values in the ImportedStatisticalForecast table. This input table is meant to hold statistical forecast values that were generated using an external tool and, once imported, can then be used by post-processing forecast logic in RapidResponse (for example, applying NPI/EOL profiles or disaggregating to the detailed part-customer level). For more information, see "ForecastImport" on page 2058. • **HoltWintersMethod**—Similar to double exponential smoothing in that it considers data points and trends within the historical data, but also accounts for seasonal trends. That is, the values for each point in the forecast and trend are further adjusted to account for seasonal demand changes. This model is the Holt-Winters multiplicative method, so it is suitable for demand that has proportional variation over a period. For a more detailed description, see "Holt-Winters multiplicative and additive" on page 2037. • **Linear**—Performs a linear regression on a set of historical data points to generate a trend line that determines statistical forecast quantities. Suitable for demand that does not fluctuate. For a more detailed description, see "Linear" on page 2039. • **MovingAverage**—Calculates the simple moving average of a specified number of previous data points to generate a constant forecast. Suitable for demand that is fairly stable and does not change much over time. For a more detailed description, see "Moving average" on page 2039. • **MultipleLinearRegression**—Performs a linear regression using multiple independent variables to predict the outcome of one dependent variable. For a more detailed description, see "Multiple linear regression" on page 2043. • **RForecast**—Uses statistical functions defined in the R statistical programming language and generates a forecast using the function that provides the best fit with the item's data. Optionally, if populated, the RParameterSet reference on the ForecastItemParameters or BestFitProfileDetail tables can be used to define specific parameter values to be passed to named functions in R. This option supports the optional R Forecast capability. For more information, see "Rforecast" on page 2039. • **StepWiseARIMA**—Identical to the ARIMA model, but all parameters are calculated automatically. Step-wise ARIMA selects the order of difference		

Table 7.22: ForecastItemParametersType (Mfg) fields

Field name	Description	Data type	Key
	through KPSS unit-root tests and selects AR order and MA order by minimizing AIC. For a more detailed description, see "Step-wise ARIMA" on page 2039. **Default value:** BestFit **Notes:** • This field was modified in Version 2016.2, Service Update 5. • This field was modified in Version 2016.2, Service Update 5 and 27.		

Table 7.22: ForecastItemParametersType (Mfg) fields

Field name	Description	Data type	Key
HoldoutPeriod UsageRule	Specifies whether a holdout period is used during best fit statistical forecasting (applicable only to items where **ForecastModel** is set to "BestFit"). The holdout period is made up of a number of intervals immediately prior to **RunDate** that are held out (excluded) when fitting statistical models. Instead, historical data in the holdout period is used to evaluate simulated forecasts generated based on models fitted against historical demands before the holdout period. The model that most accurately predicts the actuals in the holdout period (based on the chosen fit measure), is then used to generate the statistical forecast. The duration of an item's holdout period is set by the **BestFitHoldoutPeriodIntervalCount** field on the **ForecastItemParameters** table. Valid values are: • **Ignore**—No holdout period is assumed, and the **BestFitHoldoutPeriodIntervalCount** field is ignored. Each statistical model is fitted against the full range of historical data being considered and the model with the least error is used to generate the forecast. This setting corresponds to how best fit forecasting was always performed in versions prior to 2015.3. • **SimpleHoldout**—The holdout period is used in best fit forecasting. Each model has a single set of fitted parameters generated based on historical data before the holdout period, and then used to generate a simulated forecast in the holdout period. The forecast is then compared against historical actuals from intervals in the holdout period. • **Simulation**—The holdout period is used in best fit forecasting. Each model has multiple sets of fitted parameters generated from a rolling window of data that begins in the area before the holdout period and moves later. Each set of parameters then generates a forecast value for comparison against actuals from a specific interval in the holdout period. This means that actuals later in the holdout period are compared against models fitted to more recent data. **Default value:** Ignore If **BestFitHoldoutPeriodIntervalCount** is set to 0 (zero) or less, then this setting is treated as if it were set to "Ignore". Also, if there is an invalid value in **BestFitHoldoutPeriodIntervalCount** then an error is reported and no statistical forecast generated (for example, this might occur if the value specified is greater than the range of historical data being considered). **Note:** For more information about using this field, see "Using best fit with a holdout period" on page 2053.	String (Enum)	

Table 7.22: ForecastItemParametersType (Mfg) fields

Field name	Description	Data type	Key
IntervalsCalendar	The calendar used to bucket actuals and generate the statistical forecast. Typically, this might be set to a Weekly or Monthly calendar. **Referenced table:** Calendar	Reference	
ModelConstant Usage	Controls whether forecast model constants (alpha, beta, gamma, and so on) are calculated by RapidResponse or taken from values that were previously calculated and are stored in an input table. If values are taken from an input table, the values are taken from either of the following tables: **ForecastItemFitOutput** or **ForecastItemParametersFitOutput**. In addition, for forecast items that are using Multiple Linear Regression or the Elastic Net forecast model to generate a statistical forecast, this field also determines whether constants are calculated or the values are taken from the ForecastItemParametersRegressionCoefficient table. Valid values are: • **Calculate**—Forecast model constants are calculated by RapidResponse. • **Use**—Use model constants given in the **ForecastItemFitOutput** table or **ForecastItemParametersFitOutput** tables. For Multiple Linear Regression or the Elastic Net, use regression coefficients reported in the **ForecastItemParametersRegressionCoefficient** table. **Note:** The "Use" option is not supported when **ForecastModel** is set to Rforecast or ARIMAX.	String (Enum)	
TrendDecay FactorRule	The value that determines if a decay factor is added to dampen or eliminate a forecast trend. You can apply trend decay to the following statistical forecasting methods: • Double exponential smoothing • Elastic Net • Holt-Winters multiplicative • Holt-Winters additive • Multiple Linear Regression The decay factor is specified in the **TrendDecayFactor** field on the **ForecastItemParameters** table. Valid values are: • **Use**—The decay factor should be added to the forecast calculation. • **Ignore**—The decay factor should not be added to the forecast calculation. **Default value**: Ignore	String (Enum)	
Value	A unique identifier for this record. This field is referenced from the **Type** field on the **ForecastItemParameters** table.	String	Yes

Table 7.22: ForecastItemParametersType (Mfg) fields

Field name	Description	Data type	Key
ForecastItem Parameters	Set of **ForecastItemParameters** records that reference this ForecastItemParametersType value.	Set	

Note: For more information about statistical forecast models and fit measures, see "Statistical forecasting" on page 2019.

HistoricalDemandCategoryType table

The **HistoricalDemandCategoryType** table is used to define how demand data associated with a given **HistoricalDemandCategory** value is processed in RapidResponse. This table supports Sales and Operations Planning in RapidResponse.

Table 7.23: HistoricalDemandCategoryType (Mfg) fields

Field name	Description	Data type	Key
AggregationRule	If ProcessingRule is set to "Target", this field is used to set how targets are aggregated. Valid values are: • **Average**—targets are aggregated as average values. • **None**— category is not used for aggregating targets. • **Sum**— targets are aggregates sum of values.	String (Enum)	
Description	A description of this HistoricalDemandCategoryType record.	String	
Disaggregation QuantityRule	The value that determines whether historical actuals or the consensus forecast should be used to calculate forecast disaggregation rates for categories of this type. Valid values are: • **Actuals**—Historical actuals, from a specified historical demand category, should be used for calculating disaggregation rates for forecast categories of this type. • **ConsensusForecast**—The consensus forecast, for the applicable part customer, should be used for calculating disaggregation rates for forecast categories of this type. **Default value**: Actuals	String (Enum)	

Table 7.23: HistoricalDemandCategoryType (Mfg) fields

Field name	Description	Data type	Key
EventAllow Negative	Specifies whether event phases can apply forecast quantity adjustments that result in a negative value. If this field is set to "No," forecast items belonging to this type of demand category cannot have their forecasts reduced below zero by event phases. For more information about event phases, see "Event Management" on page 2109. **Default value:** No **Note:** Regardless of this setting, an event phase cannot adjust the unit price of an item below zero. **Note:** This field was added in Version 2016.2.	Boolean	

Table 7.23: HistoricalDemandCategoryType (Mfg) fields

Field name	Description	Data type	Key
ProcessingRule	Specifies how the historical demand category is used in RapidResponse, and how it affects consensus forecast calculations. Valid values are: • **Actual**—category is used for storing historical demand actuals. Values in this category can be used in calculating the statistical forecast. Ignored by consensus forecast calculations. • **Forecast**—category is used for storing streams of forecast demands or forecast adjustments. Values in this category can be used towards calculating the consensus forecast(based on the specified ConsensusForecastWeight value). Note that adjustment and override values specified in other historical category types can subsequently be used to modify or replace the calculated consensus forecast. • **ForecastOverride**—category is used for specifying values that override the calculated consensus forecast (weights are ignored). Note that this type of override can be modified by a RebalancingAdjustment or overridden by a RebalancingForecastOverride. • **None**—demands in this category are not used in any sales and operations planning calculations. Ignored by consensus forecast calculations • **RebalancingAdjustment**—category is used to increase or decrease either the **ConsensusForecast.CalculatedQuantity** or the **ForecastOverride** value (if used) during the demand and supply balancing phase (weights are ignored). Note that adjustments of this type are ignored if a RebalancingForecastOverride is specified. • **RebalancingForecastOverride**—category is used for specifying values to override the calculated consensus forecast during the demand and supply balancing phase (weights are ignored). Note that this type of override takes precedence over a ForecastOverride as well as any RebalancingAdjustment values that were applied. • **Target**—category is used for defining target metric values against which the S&OP annual plan is measured. Ignored by consensus forecast calculations	String (Enum)	

Table 7.23: HistoricalDemandCategoryType (Mfg) fields

Field name	Description	Data type	Key
UnitType	Specifies whether quantities or monetary values are used as historical demand or forecast targets. Valid values are: • **Quantity**—Values in the **Quantity** fields of the **ForecastDetail** and **HistoricalDemandSeriesDetail** tables are used as targets for historical demands and forecasts. • **Value**—Values in the **Value** fields of the **ForecastDetail** and **HistoricalDemandSeriesDetail** tables are used as targets for historical demands and forecasts. **Default value**: Quantity	String (Enum)	
Value	A unique identifier for this record. This field is referenced form the **Type** field on the **HistoricalDemandCategory** table.	String	Yes
HistoricalDemand Categories	Set of **HistoricalDemandCategory** records that reference this HistoricalDemandCategoryType value.	Set	

IMConfiguration table

This table defines the settings related to the Inventory Management application. It contains values which defines default targets, calendars, and IQR transitions. There should never be more than one record in this table.

Table 7.24: IMConfiguration (Solutions) fields

Field name	Description	Data type	Key
DefaultCustomer ServiceLevelTarget	The default customer service level target. Used when no On Time To Commit or On Time to Request target has been set for a part.	Quantity	
DefaultInventory QualityRatioTarget	The default IQR target. Used when no IQR target has been set for a part. The IQR target is set by inventory personnel in the **S&OP Annual Plan** workbook.	Quality	
DefaultSurplus Transition	When no PeriodsOfSupplyMaximum target is set, the point that inventory would be determined surplus.	Integer	
HorizonCalendar	The calendar used to define the Inventory Management planning horizon. **Referenced table:** Calendar	Reference	

Table 7.24: IMConfiguration (Solutions) fields

Field name	Description	Data type	Key
InventoryQuality RatioCalendar	Used to define the period type for the transitions between IQR categories. For example, if the calendar is months and the slow moving transition is 3, the transition to slow moving will occur at 3 months. **Referenced table:** Calendar	Reference	
ObsoleteTransition	The point that inventory would be considered obsolete instead of slow moving. Used only when **UseObsoleteTransition** is set to "Y".	Integer	
PeriodsOfSupply TargetCalendar	Used to define the target calendar for the **HistoricalDemandHeader** categories of PeriodsOfSupplyMinimum and PeriodsOfSupplyMaximum. **Referenced table:** Calendar	Reference	
RunDate	A reference to a calendar used to set the current system date (typically, this might be a calendar that has only one date belonging to it). The calculated **FirstDate** field on this calendar is then used in determining the starting point for the inventory management planning horizon. **Referenced table:** Calendar	Reference	
SlowMoving Transition	The point that inventory would be determined slow moving instead of surplus.	Integer	
UseObsolete Transition	Indicates whether to use a transition point from slow moving to obsolete. Valid values are: • **N**—Supply will only be considered obsolete if the total demand on the part is 0. • **Y**—The obsolete transition point is used. **Default value:** N	Boolean	
VisibleFuture Periods	Number of future periods to show in the Inventory Management planning horizon.	Integer	
VisibleHistorical Periods	Number of historical periods to show in the Inventory Management planning horizon.	Integer	
IMFutureHorizon	A calculated field indicating the latest date to show in the Inventory Management planning horizon.	Date	
IMPastHorizon	A calculated field indicating the earliest date to show in the Inventory Management planning horizon.	Date	

IncrementalRule table

This table is referenced by the Part table and holds values that can be used to turn incremental availability calculations on or off for each part. For more information about incremental availability, see "Incremental availability calculations" on page 1476.

Table 7.25: IncrementalRule (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this IncrementalRule record. **Referenced table:** ControlSet	Reference	Yes
Description	A description of the incremental availability setting.	String	
ProcessingRule	Specifies whether incremental availability calculations are performed for parts using this setting. Valid values are: • **On**—Incremental availability is on. This means that supply orders for the part can be split if material becomes available over time, rather than all at once, or if constraint occurs in multiple periods. This value can be overridden on a supply-by-supply basis using the SupplyStatus.IncrementalSplit field. • **Off**—Incremental availability is off. Supply orders cannot be split with respect to material availability. **Default value**: Off	String (Enum)	
Value	A unique identifier for the incremental availability setting.	String	Yes
Parts	Set of **Part** records that reference this IncrementalRule value.	Set	

InventoryTransferType table

The **InventoryTransferType** table is referenced by the **InventoryTransfer** table, and contains rules that determine how inventory transfers are handled in RapidResponse. For example, each rule defines the status of the associated inventory transfers (already received, still in-transit, or so on), and whether that inventory transfer record should be processed by RapidResponse analytics.

Table 7.26: InventoryTransferType (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this InventoryTransferType record. **Referenced table:** ControlSet	Reference	Yes
Description	A description of this type of inventory transfer.	String	
ProcessingRule	Determines whether inventory transfers using this setting are processed by RapidResponse analytics. Valid values are: • **Ignore**—inventory transfers using this setting are not processed by RapidResponse analytics. • **Use**—inventory transfers using this setting are processed by RapidResponse analytics. **Default value**: Use	String (Enum)	
Status	The status of inventory transfers using this setting. This determines if the inventory transfer quantity should be subtracted from on hand inventory at the sourcing site (TransferPart), and supply created at the destination site (Part). Valid values are: • **ByDate**—Calculates the status to use based on the ship and stock dates of the inventory transfer as follows: "**InTransit**" is used if *ShipDate* < *Transfer Part.PlanningCalendars.DataDate* and *StockDate* >= *Part.PlanningCalendars.DataDate*. "**NotReleased**" is used if *ShipDate* >= *TransferPart.PlanningCalendars.DataDate*. "**Received**" is used if *StockDate* < *Part.PlanningCalendars.DataDate*. • **InTransit**—An active inventory transfer that has left the sourcing site, but not yet arrived at the destination site. RapidResponse will create supply for the Part at the destination site, but assumes that inventory at the sourcing site has already been decreased, and so no dependent demand is created for the TransferPart. • **NotReleased**—An active inventory transfer that has not yet left the sourcing site. RapidResponse creates supply for the Part at the destination site, and creates dependent demand for the TransferPart. • **Received**—An inactive inventory transfer that occurred in the past. RapidResponse assumes that inventory at the sourcing site has already been decreased, and also does not create supply at the destination site. **Default value**: NotReleased	String (Enum)	
Value	A unique identifier for this inventory transfer setting.	String	Yes

Table 7.26: InventoryTransferType (Mfg) fields

Field name	Description	Data type	Key
InventoryTransfers	Set of **InventoryTransfer** records that reference this InventoryTransferType value.	Set	

IPOConfiguration table

This table contains settings that support the Inventory Planning and Optimization application in RapidResponse. This table contains exactly one record, and can be modified on a scenario-by-scenario basis by either System Administrators or Data Administrators.

It contains default values used when configuring safety stock items such as the outlier type, the threshold, the smoothing intervals settings, and the multi-echelon processing rules. For more information about the default outlier type, see the **OutlierType** table. For more information about the multi-echelon processing rules, see the **MultiEchelonSafetyStockRule** table.

This table was added in Version 2016.2 Service Update 10 to support the **Inventory Planning and Optimization** application.

Table 7.27: IPOConfiguration fields

Field name	Description	Data type	Key
DefaultMEIO NoInventoryRule	The default multi-echelon "NoInventory" processing rule. **Referenced table**: MultiEchelonSafetyStockRule (Nullable)	Reference	
DefaultMEIO UseRule	The default multi-echelon "Use" processing rule. **Referenced table**: MultiEchelonSafetyStockRule (Nullable)	Reference	
DefaultOutlierType	A reference to the default outlier type, whose set of processing rules define how outliers in historical data are identified and subsequently processed for parts configured as safety stock items. **Referenced table**: OutlierType (Nullable)	Reference	
DemandOutlier Threshold	The default (minimum) number of standard deviations away from the mean a demand quantity must be in order to be considered an outlier. Any outliers detected are then removed, smoothed, or ignored, as specified by the setting in the **Type.DemandOutlierProcessingRule**.	Quantity	
Smoothing IntervalsAfter	When smoothing demand outliers, this indicates the default number of **Type.IntervalsCalendar** periods forward over which to spread the values. This occurs after any backward spreading.	Integer	
Smoothing IntervalsBefore	When smoothing demand outliers, this indicates the default number of **Type.IntervalsCalendar** periods backward over which to spread the values. This occurs before any forward spreading.	Integer	

MEIOLeadTimeType table

The **MEIOLeadTimeType** table sets how parts configured for variable/random lead times in multi-echelon safety stock calculations have their average and standard deviation of lead time parameters calculated.

Note that the calculated lead time parameter values resulting from these settings can be seen in the **CalcStandardDeviation** and **CalcAverage** fields on the **MEIOLeadTime** table.

Table 7.28: MEIOLeadTimeType (Mfg) fields

Field name	Description	Data type	Key
Category	Specifies the category that historical supply records in the **HistoricalSupplyActual** table should belong to in order to be collected and used in calculating lead time parameters. This reference only needs to be populated if **ProbabilityDistribution** is set to "Normal" and **StandardDeviationRule** is set to "Calculate". **Referenced table:** HistoricalSupplyCategory (Nullable)	Reference	
ControlSet	The control set associated with this **MEIOLeadTimeType** record. **Referenced table:** ControlSet	Reference	
DistributionProfile Rule	For discrete probability distributions, this setting determines how the individual distribution profile points (as found in the **Value** field of the **MEIOLeadTimeDistributionProfilePoint** table) are interpreted. Valid values are: • **LeadTime**—Each distribution profile point represents an actual lead time value. • **Multiplier**—Each distribution profile point should be interpreted as a multiplier with lead time then calculated as *AverageLeadTime* * *Value*. This setting allows for the same profile to be used for parts with different average lead time values. **Default value:** LeadTime **Note:** This setting is only applicable when **ProbabilityDistributionRule** is set to "Discrete".	String (Enum)	

Table 7.28: MEIOLeadTimeType (Mfg) fields

Field name	Description	Data type	Key
Probability Distribution	Specifies the probability distribution model that lead time values are assumed to follow, and hence how lead time parameters are calculated for this type. Valid values are: • **Discrete**—Lead time is modeled using a discrete probability distribution. Actual lead time values and their associated probabilities come from the distribution profile referenced by **MEIOLeadTime.DistributionProfile** (with the setting in the **DistributionProfileRule** field used to determine how the actual profile points are interpreted). • **Ignore**—Lead time variability is ignored for this type. In other words, it will use the fixed lead time value from the **MEIOLeadTime** table, but it will ignore the standard deviation so that there is no probability distribution. However, it may use a lead time value from the **PartSource** table only if there's no applicable record in **MEIOLeadTime** table. • **Normal**—Lead time is modeled using a normal probability distribution. Based on the setting in the **StandardDeviationRule** field, lead time parameters are either set to values provided as input on the **MEIOLeadTime** record or calculated based on historical supply records from the referenced **Category**. **Default value**: Ignore **Note:** For information about configuring lead time parameters for multi-echelon safety stock calculations, see "Configure multi-echelon lead time parameters (optional)" on page 1960.	String (Enum)	

Table 7.28: MEIOLeadTimeType (Mfg) fields

Field name	Description	Data type	Key
StandardDeviation Rule	For normal probability distributions, this setting determines how the average and standard deviation of historical supply lead times is determined (either calculated based on history or set to manually provided input values). Valid values are: • **Calculate**—average and standard deviation of lead time is calculated based on historical supply actuals. In order to be used in these calculations, historical supplies for a given part must belong to the same historical supply category as is referenced in the **Category** field, and those historical records must reference the same **Source** value as is referenced through **MEIOLeadTime.PartSource**. • **CoefficientOfVariation**—average of lead time is set to the input value provided in **MEIOLeadTime.Average** while the value in **MEIOLeadTime.StandardDeviation** is assumed to be the coefficient of variation. Therefore, standard deviation of lead time is calculated as **MEIOLeadTime.Average * MEIOLeadTime.StandardDeviation**. • **Manual**—average of lead time is set to the input value provided in **MEIOLeadTime.Average** while the standard deviation of lead time is set to the input value provided in **MEIOLeadTime.StandardDeviation**. **Default value:** Manual **Note:** This setting is only applicable when **ProbabilityDistributionRule** is set to "Normal".	String (Enum)	
Value	A unique string identifier for this control setting.	String	Yes
Items	Set of **MEIOLeadTime** records that use this control setting.	Set	

MPSConfiguration table

The **MPSConfiguration** table contains settings that support the MPS application in RapidResponse. This table contains exactly one record, and can be modified on a scenario-by-scenario basis to model various MPS planning scenarios. For example, the duration of the MPS planning horizon might be changed.

The settings in the **MPSConfiguration** table are used in various MPS resources, such as the **Master Scheduling** workbook, but do not impact any analytic calculations. Note also that the settings in this table act as global defaults, some of which can be overridden at the part level using corresponding fields in the **PartSolution** table.

Table 7.29: MPSConfiguration (Solutions) fields

Field name	Description	Data type	Key
AutoFirmWindow	Indicates the length of the auto-firm window. The auto-firm window defines a period after the MPS planning horizon in which a workbook command automatically converts planned orders into firm MPS orders. This value is added from the start of the latest **SOPAnalyticsConfiguration.CycleCalendar** interval that is contained in the MPS horizon. This field value should be expressed in **CycleCalendar** units. This field acts as a global default for all parts where **PartSolution.MPSAutoFirmWindow** is set to -1. Otherwise, if a non-negative value is provided in the **MPSAutoFirmWindow** field then it is used for the part. The part's effective MPS auto-firm window, from either the **PartSolution** or **MPSConfiguration** tables, is then reported in **PartSolution.EffectiveMPSAutoFirmWindow**.	Integer	
Calendar	A reference to the Calendar whose intervals define bucket sizes in the MPS application. For example, this might by a Weekly calendar. **Referenced table:** Calendar	Reference	
FrozenWindow	Indicates the length of the MPS frozen window in **Calendar** intervals. The frozen window is then defined starting from **CalcStartDate** and ending after the number of intervals specified here. This window represents a near-term portion of the planning horizon within which is strongly recommended to not make any changes to MPS orders (for example, because it may not be feasible to change material or capacity commitments). This field value acts as a global default for all parts where **PartSolution.MPSFrozenWindow** is set to -1. Otherwise, if a non-negative value is provided in the **MPSFrozenWindow** field then it is used for the part. The part's effective MPS frozen window, from either the **PartSolution** or **MPSConfiguration** tables, is then reported in **PartSolution.EffectiveMPSFrozenWindow**.	Integer	
Horizon	Indicates the length of the MPS planning horizon in **Calendar** intervals. The planning horizon is then defined starting from **CalcStartDate** and ending after the number of intervals specified here. Within this horizon, MPS orders are assumed to be fully under the authority of the master scheduler. This field value acts as a global default for all parts where **PartSolution.MPSHorizon** is set to -1. Otherwise, if a non-negative value is provided in the **MPSHorizon** field then it is used for the part. The part's effective MPS horizon, from either the **PartSolution** or **MPSConfiguration** tables, is reported in **PartSolution.EffectiveMPSHorizon**.	Integer	

Table 7.29: MPSConfiguration (Solutions) fields

Field name	Description	Data type	Key
RunDate	A reference to a calendar used to set the current system date (typically, this might be a calendar that has only one date belonging to it). The calculated **FirstDate** field on this calendar is then used in determining the starting point for the MPS planning horizon. **Referenced table:** Calendar	Reference	
Tolerance	Specifies whether tolerance settings in the **ToleranceInterval** and **ToleranceCalendar** fields are used by MPS resources to determine whether a supply is considered late. Valid values are: • **N**—tolerance settings are not used in determining order lateness. A supply is considered late if its available date is after the due date on the demand it satisfies. • **Y**—tolerance settings are used in determining order lateness. A supply is considered late if its available date is more than the specified number of **ToleranceCalendar** intervals after the demand due date. **Default value:** N	Boolean	
ToleranceCalendar	A reference to the calendar that determines how the **ToleranceInterval** value is interpreted. **Referenced table:** Calendar	Reference	
ToleranceInterval	This field sets the maximum limit on lateness for MPS orders. It is used in certain resources that use measures of lateness to report whether the master schedule is being achieved. If an MPS order is more than this number of **ToleranceCalendar** intervals late, then it is considered outside of tolerance and hence reported as late (subject to the setting in the **Tolerance** field).	Integer	
StartOffset	Number of **Calendar** intervals after the current system date (**RunDate.FirstDate**) at which to begin the MPS planning horizon.	Integer	
CalcEndDate	A calculated field indicating the end of the MPS planning horizon. This date is set by adding the value in the **Horizon** field to **CalcStartDate**.	Date	

Table 7.29: MPSConfiguration (Solutions) fields

Field name	Description	Data type	Key
CalcStartDate	A calculated field indicating the start of the MPS planning horizon. This date is set by adding the value in **StartOffset** to the current system date (as determined by the referenced value in **RunDate.FirstDate**).	Date	

MUEPoolNettingType table

The **MUEPoolNettingType** table supports the Model-Effectivity, Unit-Effectivity, and Pooling analytics and thereby allows finer control over processing rules for model, unit, and pool. This table is also used to enable attribute-based planning at the part table.

This information in the table is separated from the **PartType** table to allow generic part types like Make and Buy to be retained, while allowing for different netting rules within the type.

Table 7.30: MUEPoolNettingType (Mfg) fields

Field name	Description	Data type	Key
AttributeExcess Rule	When using attribute-based planning, this setting controls how excess available supply from planned orders created to satisfy one demand can be used (or not) by other subsequent demands. • **Ignore**—excess supply from a planned order created to satisfy one demand can only be used by other demands if their demand attributes match those of the original demand. That is, even if the supply attributes on the excess planned order (as injected from the **PartSource**) satisfy the requirements of a subsequent demand, but the demand attributes on that demand do not match those on the original demand, then the excess supply is not used. This setting corresponds to how attribute-based planning also handled excess planned supply prior to Version 2016.2. • **Use**— excess supply from a planned order created to satisfy one demand can be used by other demands as long as the supply attributes on the planned order (as injected from the **PartSource**) satisfy the attribute requirements of those demands. However, there is no need for the demand attributes on those other demands to match those on the original demand. This setting can help reduce the excess supply that might result from certian configurations of attribute-based planning (for example, when used with lot-sizing requirements). Note also that if using this setting, each PartSOurce should not only have a supply attribute defined (for demand-supply attribute matching), but also a demand attribute which can be propagated to demands on lower levels. **Default value**: Ignore **Note:** This field was added in Version 2016.2. For an example of its usage, see "Example 3: Allotments with attributes and excess supply" on page 1839.	String (Enum)	
AttributeFlowTo Common	If using attribute-based forecast consumption, this setting determines how actual demands can consume forecast based on their respective sets of attribute values. Valid values are: • **Forecast**—actual demand first consume from those forecast demands to which they have matching attribute values. If there is any remaining actual, then forecast consumption continues on any forecast demands that do not have attribute values defined on them. • **Ignore**—actual demands only consume from those forecast demands to which they have matching attribute values. **Default value:** Ignore	String (Enum)	

Table 7.30: MUEPoolNettingType (Mfg) fields

Field name	Description	Data type	Key
AttributeRule	Used to enable or disable attribute-based calculations at the part level. Attributes can be added and used to identify relevant characteristics of demands or supplies which are then used to refine certain analytic calculations. Attributes are supported in supply allocation, forecast consumption, and forecast adjustment calculations. For example, a given customer's demands might only be able to receive supply containing components sourced from particular locations, or a given customer's forecast might only be eligible to be consumed by actual demands from that same customer. The actual rules that define relationships between attributes and how they are used in analytic calculations are set in the **AttributeMap** table. This field is then used to set the specific parts that should utilize those attribute relationships. Valid values are: • **Ignore**—attribute-based planning is disabled for parts using this type. If attribute-based planning logic is not being used at all, this setting can be left for all parts. • **Net**—attribute-based planning is enabled for parts using this type. This value should be set for any parts expected to either require attribute-based planning. **Default value**: Ignore Note also that supply attributes defined on the **PartSource** table can be propagated to all dependent demands under a given planned order regardless of the setting in this field. This field only controls whether attributes are used in planning calculations for a given assembly or component, not whether the attribute values themselves can be propagated through parts in the product structure.	String (Enum)	
ControlSet	The control set associated with this MUEPoolNettingType record. **Referenced table:** ControlSet	Reference	Yes
Description	A description of the type of Model Effectivity, Unit Effectivity, or Inventory Pooling configuration. This field is an explanation of the Value field. **Default value**: blank string	String	

Table 7.30: MUEPoolNettingType (Mfg) fields

Field name	Description	Data type	Key
ModelRule	Identifies whether to process Model data. Regardless of the value of ModelRule, it is treated as Ignore unless Model-Unit Effectivity is enabled. Valid values are: • **ExplodeOnly**—no model nettings is performed for this part, but demand can be exploded by model. Demands and supplies are processed in the "default" model, and planned orders are created in the original model of the triggering demand. The model on the supply is then respected when exploding dependent demand on the part. • **Ignore**—no model netting is performed for this part. Model information on scheduled receipts is retained and may be used for explosion, but no Model data is copied to planned supply records. (The **ScheduledReceipts.InputModel** is set to 'None'. The first model in the Model table, needs to be populated with a value of 'None'). • **Net**—align supply and demand by model. Populate **ScheduledReceipt.InputModel** in planned supply with the value of the model being netted. • **NetWithoutForecast**—align supply and demand by model in netting calculations, but ignore the model when consuming forecast (actuals consume from "common" model). This option is useful when model is important for matching supply to demand, but not included on forecast records. **Default value**: Ignore	String (Enum)	

Table 7.30: MUEPoolNettingType (Mfg) fields

Field name	Description	Data type	Key
PoolFlowTo Common	Specifies whether customer orders consume common forecast during independent and dependent demand forecast consumption. This field is also used by the Netting analytic to control where new supply is planned after using up all supply in both a customer's specified pool and the common supply pool. Valid values are: • **Ignore**—customer orders only consume forecast from the pool representing that customer's forecast. New planned orders can only be generated from part sources where the **PartSource.Pool** reference is a match for the demand pool or is "Null". • **Forecast**—customer orders first consume from the pool representing that customer's forecast. If any actual demands for that customer are left after all of the customer's forecast is consumed, then the remaining can consume from the common forecast. New planned orders can only be generated from part sources where the **PartSource.Pool** reference is a match for the demand pool or is "Null". • **NetCommon**—in forecast logic, customer specific forecast consumption is the same as with the Forecast option. In Netting logic, demand within a specific pool will be satisfied first by supply within that same pool pool, and then, if necessary, by supply in the common pool. Once supply in the common pool has been used, new supply is planned in the common pool. New planned orders can only be generated from part sources where the **PartSource.Pool** reference is either to the "Common" pool or is "Null" (part sources where **PartSource.Pool** is a match for the demand pool cannot be used). • **NetOriginal**— in forecast logic, customer specific forecast consumption is the same as with the Forecast option. In Netting logic, demand within a customer-specific pool will be satisfied first by supply in that customer's specified pool, and then, if necessary, by supply in the common pool. Once supply in the common pool has been used, new supply is planned in the (original) customer-specified pool. New planned orders can only be generated from part sources where the **PartSource.Pool** reference is a match for the demand pool or is "Null". **Default value:** Ignore	String (Enum)	

Table 7.30: MUEPoolNettingType (Mfg) fields

Field name	Description	Data type	Key
PoolRule	Identifies whether to process pool data. If Pool is not licensed then the values of Net and Optional are treated as Ignore. However, Forecast and ForecastOptional settings can be used regardless of whether Pool has been enabled. Valid values are: • **Ignore**—no Inventory Pooling is performed for this part. Pool information on scheduled receipts is retained, but no Pool data is copied to planned supply records. New supply for parts with this setting can be created by any eligible part source and planned in the pool defined by **PlanningCalendars.CommonPool** (for example, the "common" or "unpooled" pool). This common pool is then typically propagated down to other supplies in the structure. However if the **PartSource.Pool** field is populated for a part with this setting (to pooling does not apply), then that pool can potentially be injected on supplies for lower-level components that use the "Net" or "Optional" settings (rather than planning them in the common pool). • **Net**—normal Inventory Pooling is performed based on the stated pool. Pool mappings (if any) are applied, and forecast is then consumed by pool, and netting performed by pool. Pool value on planned supplies is typically populated with the value of Pool being netted (either the value mapped in PoolMap or PoolMapOverride table, or if no mappings are provided the pool value from the demand is used). Note that the specific pool and part source used for planned orders is further dependent on the **PoolFlowToCommon** setting. • **Optional**—Inventory Pooling is performed using either the mapped pool (if any) or else the common pool. That is, if the demand's pool is listed in either the PoolMap table (based on PartType) or PoolMapOverride table (based on Part) then that pool is used. Otherwise, if no matching mappings are provided, the common pool is used. Note that specific pool and part source used for planned orders is further dependent on the **PoolFlowToCommon** setting. • **Forecast**—consume forecast by Pool but do not net by Pool. Apply any specific Pool Mapping for the part or part type to Actual and Forecast demands. Consume the forecast, and then treat all supplies and demands as CommonPool. When SalesActual and SalesForecast demands are processed, they are segregated in Model, Unit, and Pool combinations based on the input values and the pool mapping. • **ForecastOptional**—consume forecast by Mapped pool (if there is any mapping available, otherwise the CommonPool is used). Netting of unconsumed forecast is done by	String (Enum)	

Table 7.30: MUEPoolNettingType (Mfg) fields

Field name	Description	Data type	Key
	CommonPool.		
SafetyStockRule	Identifies how safety stock calculations are performed for parts that have model, unit, and/or pool logic enabled. Valid values are: • **ByPool**—Safety stock calculations are enabled for all parts that have model, unit, and/or pool logic enabled. Safety stock is planned separately for each pool applicable to the part, but always using the default model and unit. Note that if using inventory pooling along with fixed safety stock requirements (where **SafetyStockQuantityRule** is set to "Fixed"), then the expected safety stock amounts might not be planned. If pools are specified on part sources, inventory, or demands, and a fixed safety stock quantity is required, it is recommended to use a **SafetyStockQuantityRule** of "TimePhasedQuantity" instead (the **TImePhasedSafety** table allows specifying safety stock levels by part and pool). • **Common**—Safety stock calculations are enabled for parts that have model, unit, and/or pool logic enabled and use either fixed or time-phased safety stock quantities (in other words, dynamic safety stock rules are ignored). Safety stock is planned for the part, but only within the common pool, default model, and default unit. • **Ignore**— Safety stock calculations are disabled for parts that have model, unit, and/or pool logic enabled. In other words, safety stock is not planned. This setting corresponds to how safety stock was always handled for parts netted by model, unit, and/or pool in versions prior to 2013.4. **Default value:** Ignore **Note:** For more information, see "Safety stock and pools" on page 1749.	String (Enum)	

Table 7.30: MUEPoolNettingType (Mfg) fields

Field name	Description	Data type	Key
UnitRule	Identifies whether to process unit data. If the Model-Unit Effectivity is not enabled, and UnitRule is 'Net', the UnitRule is processed as Ignore, otherwise the UnitRule is processed as described. Valid values are: • **Block**—perform block netting for the part.For information about block netting, see "Block netting" on page 1334. • **ExplodeOnly**—does not net by unit, but demand is exploded by unit. StartUnit is ignored when allotting supply to demand, but planned orders are generated by the StartUnit of the triggering demand. When exploding demand to lower levels, the StartUnit on ScheduledReceipts and PlannedOrders is used to determine the bill of material to use. • **Fixed**—do not net by unit, but generate new StartUnit values for planned supplies, each one using the same Part.NextUnit value • **Ignore**—no unit netting is performed for this part. StartUnit information on scheduled receipts is retained and may be used for explosion, but no StartUnit data is copied to planned supply records (the 'Unit Undefined' state is used on planned supply. StartUnit is –1) • **Increment**—do not net by unit, but generate new StartUnit values for planned supplies, by incrementing the Part.NextUnit value, if >=0. Otherwise, simply copy the Part.NextUnit value). • **Net**—align supply and demand by StartUnit (use data audits to detect supplies or demands where the quantity is greater than one). Populate StartUnit in planned supply with the value of the unit being netted. • **NetWithoutForecast**—align supply and demand by StartUnit in netting calculations, but ignore the StartUnit when consuming forecast (actuals consume from "common" unit). **Default value**: Ignore	String (Enum)	
Value	The name representing this type of Model Effectivity, Unit Effectivity, or Inventory Pooling configuration. **Default value**: blank string	String	Yes
Parts	Set of **Part** records that reference this MUEPoolNettingType value	Set	

MultiEchelonSafetyStockRule table

The **MultiEchelonSafetyStockRule** table is referenced by the **Part** table and supports multi-echelon inventory optimization. When a part is eligible to be brought into one or more multi-echelon families, the settings in this table control how that part is processed by multi-echelon safety stock calculations.

For example, individual parts can be included in, or excluded from, multi-echelon safety stock calculations (this might be useful if enabling multi-echelon calculations on a part-by-part basis).

This table is also used to configure how each part's inventory holding costs are calculated (the costs are required use by the logic that makes safety stock recommendations based on minimizing the total cost of holding inventory across a network of parts).

Table 7.31: MultiEchelonSafetyStockRule (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this **MultiEchelonSafetyStockRule** record. **Referenced table:** ControlSet	Reference	Yes
CostRule	Specifies the source of the part's cost values for use in calculating inventory holding costs. The cost value as determined by this setting is subsequently multiplied by **Part.InventoryHoldingRate** to determine the per unit cost of holding inventory for the part. Valid values are: • **RolledUp**—inventory holding costs are derived from rolled up material, labor, and/or overhead costs on the part's components. • **StdUnitCost**— inventory holding costs are derived from the part's standard unit cost value. **Default value**: RolledUp **Note:** For more information about inventory holding cost calculations, see "Calculate inventory holding costs for MEIO" on page 1996.	String (Enum)	
Description	A description of this multi-echelon safety stock rule. **Default value**: blank string	String	

Table 7.31: MultiEchelonSafetyStockRule (Mfg) fields

Field name	Description	Data type	Key
ProcessingRule	Specifies how parts using this rule are processed by multi-echelon safety stock calculations. Valid values are: • **Ignore**—ignored by multi-echelon safety stock calculations. Parts referencing this rule should not typically be brought into multi-echelon families or used in inventory optimization calculations. • **NoInventory**—used by multi-echelon safety stock calculations, but not eligible to hold inventory. Parts referencing this rule can be brought into multi-echelon families and their parameters used in inventory optimization calculations for the family. However, a recommended safety stock level is typically not calculated for these parts. • **Use**—used by multi-echelon safety stock calculations. Parts referencing this rule can be brought into multi-echelon families and used in inventory optimization calculations for safety stock items. As required, a recommended safety stock level will be calculated for these parts. **Default value**: Ignore **Note:** For examples of how this setting is used in creating multi-echelon families, see"Create multi-echelon families" on page 1990.	String (Enum)	
Value	A unique identifier for this multi-echelon safety stock rule. **Default value**: blank string	String	Yes
Parts	The set of parts that reference this **MultiEchelonSafetyStockRule** record.	Set	

MultiLevelSearchRule table

Specifies whether multi-level search logic is enabled for parts that reference a given value in this table.

When multi-level search logic is enabled for a part with multiple part sources or substitutes, the sourcing decisions made can consider all child component materials and constraints in order to help choose the path that will provide the supply either on time or least late. Otherwise, the standard sourcing logic is used (for example, when choosing a part source, source effectivity, constraints, PTF date, and sourcing rules are considered, but unlimited component availability is assumed).

Enabling multi-level search also provides support for non-blocking allocations by modifying the supply allotment process to consider sibling component availabilities. As necessary, the allocation of a given component's supply to a demand is synchronized with the supply of the demand's gating component (if any). This allows earlier supply of the gating component's sibling to be re-directed to other demands and potentially improve their availability. Otherwise, the standard allotment logic is used (for example,

component supply available dates, demand due dates, and order priorities are considered, but no knowledge of any sibling component allocations is assumed).

For more information about use of multi-level search logic and potential limitation on other analytics, see "Multi-level search logic" on page 1863.

Table 7.32: MultiLevelSearchRule (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this MultiLevelSearchRule record. **Referenced table:** ControlSet	Reference	Yes
Description	A description of this multi-level search rule. **Default value**: blank string	String	
Future Availability	Specifies how multi-level search logic should plan when an order is determined to be available at Future. Valid values are: • **Ignore**—If an order is determined to have "future" availability, then it is not planned. Thus, requirements are not driven down to lower-level components and constraint. • **Plan**—If an order is determined to have "future" availability, it is still planned thus driving requirements down to lower-level components and constraints. This setting corresponds to how planning was always performed in versions prior to 2016.2. **Default value**: Plan **Note:** This field was added in Version 2016.2, Service Update 5.	String (Enum)	

Table 7.32: MultiLevelSearchRule (Mfg) fields

Field name	Description	Data type	Key
LoggingRule	Indicates whether to log and report details of end-item demands which multi-level search logic determined couldn't be planned within a given lateness tolerance and were therefore left unsatisfied (demands can be left wholly or partially unsatisfied if their DemandType.PlanningRule is set to "Partial", otherwise they should always be planned even if late). Along with details of the end-item demands that couldn't be planned or satisfied, the specific trial supplies that ultimately contributed to those demands being left unsatisfied is reported. For example, an end-item demand might be left unsatisfied because there was insufficient constraint available to allow a lower-level component supply to be planned when needed. Valid values are: • **None**—details of demands that were left unsatisfied and the trial supplies that couldn't be planned in time to satisfy those demands are not reported. • **UnsatisfiedDemand**—details of demands that were left unsatisfied, and the trial supplies that couldn't be planned in time to satisfy those demands, are reported. Table such as **MLSActivity**, **TrialPlannedOrder,** and **TrialConstraintShortage** can be populated. **Default value:** Ignore **Note:** This field was added in Version 2016.2, Service Update 5.	String (Enum)	
NewPurchasesCost	Specifies whether rolled up material cost from purchase orders is considered during the multi-level source selection process. This setting can be used to help avoid selecting very low-yielding and/or expensive part sources. Valid values are: • **Ignore**—Part source selection criteria does not include rolled up material cost from purchase orders. • **UseBeforeTarget**—Part source selection criteria considers rolled up material costs from purchase orders before it considers **MLSPreTargetSequence** and **Target** values. That is, if two part sources of the same priority can provide supply equally well and component supply types/depth are equivalent, then the one with the lower rolled-up material cost from component purchase orders would be chosen (regardless of targets). **Default value:** Ignore **NOTE**: This field was added in Version 2016.2, Service Update 23.	String (Enum)	

Table 7.32: MultiLevelSearchRule (Mfg) fields

Field name	Description	Data type	Key
PartSourceLimit	The maximum number of effective part sources that can potentially be evaluated when planning supply to satisfy a given demand for the part. Because large numbers of part sources typically lead to multi-level search logic performing a larger number of trial operations, placing a practical limit on the number of sources evaluated can improve runtime performance. In particular, if there is a very large number of low-yielding part sources, then setting this field appropriately can have a performance benefit with very little impact on solution quality. Any negative value, or zero (0), indicates that no limit should be placed on the number of effective part sources. **Default value**: 100 **NOTE**: This field added in Version 2016.2, Service Update 17. **NOTE**: This limit applies to effective part sources only (those part sources where a given demand date falls within the effective in and out dates). Any ineffective part sources are not counted against the specified limit.	Integer	
ProcessingRule	Indicates whether child component materials and availability are considered when sourcing supply of part from multiple part sources or substitutes, and whether sibling component allotments are considered when allocating supply of the part to the demands that require it. Valid values are: • **Ignore**—standard sourcing and supply allotment logic is used. That is unlimited child component availability is assumed when making supply sourcing decisions, and sibling component supplies are allocated to demands independently of one another. • **Use**—standard sourcing logic is modified to include considerations of component materials and availability when sourcing supply from multiple potential part sources or substitutes, and standard supply allotment logic is modified to include considerations of sibling component allotments when allocating a part's supply to higher-level demands. Note that even if an assembly part is set to "Use", multi-level search logic stops at component part(s) in its structure that are set to "Ignore". **Default value**: Ignore	String (Enum)	

Table 7.32: MultiLevelSearchRule (Mfg) fields

Field name	Description	Data type	Key
Scheduled SupplyRule	In multi-level search logic, this field is used to specify whether part sources where component supply comes from on hand inventory should be preferred to part sources where components come from scheduled supply (scheduled receipts, inventory transfers, and so on). For example, when two part sources of the same priority are eligible to source a supply on time (with no preference based on input supply level), then the lowest level of component supply used by each is compared. At this level of source selection, on hand and scheduled component supply are always preferred to new planned orders, however the setting in this field determines whether there is a preference between on hand supply and scheduled supply. Valid values are: • **EqualToOnHand**—When evaluating the lowest level of component supply used by part sources, on hand inventory and scheduled supply are treated equally (both are preferred to new planned orders). • **PreferOnHand**—When evaluating the lowest level of component supply used by part sources, on hand inventory is preferred to scheduled supply (both are preferred to new planned orders). **Default value:** PreferOnHand **Note:** This field was added in Version 2016.2, Service Update 8.	String (Enum)	

Table 7.32: MultiLevelSearchRule (Mfg) fields

Field name	Description	Data type	Key
ShortTerm Excess	Specifies how to handle potential short-term excess inventory that can result from using multi-level search logic along with priority planning, dynamic safety stock, lot-sizing, or constraints. Valid values are: • **Allow**— Short-term excess resulting from by pre-building supply is allowed. This setting corresponds to how planning was always performed in versions prior to 2016.2. • **Reduce**—Attempts are made to reduce short-term excess resulting from pre-building supply. Multi-level search logic might pull-in or delay supplies in order to reduce near-term excess. **Default value:** Allow **Note:** This field was added in Version 2016.2, Service Update 5. **Note:** When using the "Reduce" setting, the pulling in or delaying of planned orders cannot move them outside of their part source's effectivity. Thus in cases of multiple part sources with short date effectivity ranges, the use of the "Reduce" setting can potentially introduce temporary excess supply and/or shortages.	String (Enum)	

Table 7.32: MultiLevelSearchRule (Mfg) fields

Field name	Description	Data type	Key
Source EffectivityRule	Indicates which planned supply dates are compared against the effective in and out dates on a part source during multi-level source selection. This setting therefore determines whether rolled up component availability should be used in the determination of assembly part source effectivity, and hence whether component availability outside of an assembly's part source effectivity can result in the assembly's demand being left unsatisfied. Valid values are: • **AvailableDate**—Effective dates on a part source are first compared against the planned order due date and then against the date that multi-level sourcing logic expects the order to be available. If found to be effective during these Netting calculations, the part source effective dates are further compared against the order's available date as calculated by CTP logic. Thus, planned component availability is used in determining assembly part source effectivity, and if planned component availability falls outside the effective range, the part source will not be selected (even if this means a demand will be planned late or left unsatisfied). Note that if planned component availability falls outside of assembly part source effectivity, the assembly's demand is left unsatisfied and an exception with Type of "MLSSourceEffectivity" is logged in the DemandException table. However, if planned component availability falls within assembly part source effectivity but actual component availability (as determined in CTP logic) subsequently falls outside of assembly part source effectivity, no demand exception is logged but the demand is still given an AvailableDate of "Future". • **DueDate**—Effective dates on a part source are compared against planned order due date only. Thus, planned component availability is not used in determining part source effectivity on an assembly. If a part source is effective on the supply due date, but some or all component availability is expected to fall outside that effective range, the part source can still be selected. • **PlannedAvailableDate**—Effective dates on a part source are first compared against the planned order due date and then against the date that multi-level sourcing logic expects the order to be available. Thus, this option considers planned component availability during source selection for an assembly. If a part source is effective on the supply due date, but some or all component availability is expected to fall outside the effective range, the part source will not be selected	String (Enum)	

Table 7.32: MultiLevelSearchRule (Mfg) fields

Field name	Description	Data type	Key
	(even if this means a demand will be planned late or left unsatisfied). Note that if a part's demand is left unsatisfied because planned component availability falls outside part source effectivity, an exception with **Type** set to "MLSSourceEffectivity" is logged in the **DemandException** table. **Default value:** DueDate **Note:** This field was added in Version 2016.2, Service Update 4. The DueDate option corresponds to how multi-level source selection was always done in earlier versions. For more information about this field and an example of its usage, see "Multi-level part source effectivity" on page 1865.		

Table 7.32: MultiLevelSearchRule (Mfg) fields

Field name	Description	Data type	Key
Unsatisfied Demand Logged QuantityRule	When reporting unsatisfied demands due to partial planning logic used with multi-level search, this field controls the extent of the logging related to those unsatisfied demands and the supplies that couldn't satisfy them on time or within lateness tolerance. This can affect the number of records generated in tables such as MLSActivity, TrialPlannedOrder, and TrialConstraintShortage. Valid values are: • **FirstLatePortion**—Only the first portion of the supplies that will be planned late to satisfy the demand within tolerance is reported. For example, if constraint causes supply of a given component is planned to be available in five different portions and three of those portions fall on dates outside of the driver part's lateness tolerance, only the first of those segments is logged and the other two excluded from logging. • **FullQuantityPrimaryPath**—The entire unsatisfied demand quantity, along with all supply portions that would be too late to satisfy it on time (or within lateness tolerance), is reported. Constraint consumption occurs as normal and, in case when there is a lack of constraint available, demand logging might not continue all the way to lower levels in the structure. With this setting, all supplies logged as being outside of tolerance for the unsatisfied demand quantity are reported as being sourced from the primary part source at each level. • **FullQuantityPrimaryPathAfterNetting**—The unsatisfied demand quantity and supply portions late to satisfy it are reported after Netting logic completes and in the order that the demands were shorted. On-time input supply consumption is allowed, but only supplies leftover from the usual netting process can be used. Constraint consumption is disabled during the downwards pass (thus constraint availability does not change where dependent demands get exploded). **Default value:** FirstLatePortion **Note:** This field was added in Version 2016.2, Service Update 8. For details about how the primary part source (path) is determined when logging the full unsatisfied demand quantity, see "Primary part source used in MLS logging" on page 1867.	String (Enum)	
Value	A unique identifier for this multi-level search rule. **Default value**: blank string	String	Yes
Parts	The set of parts that reference this MultiLevelSearchRule record.	Set	

OFConfiguration table

The **OFConfiguration** table contains settings used by resources available with the Order Fulfillment application. For example, it allows defining the maximum threshold for both supply-related and customer-requested changes allowed against any single line item before that line is flagged for attention in certain Order Fulfillment resources.

Table 7.33: OFConfiguration (Solutions) fields

Field name	Description	Data type	Key
ActualsCategory	The category used to indicate closed customer orders. Order fulfillment resources that report historical data do so based on historical demand records that belong to this category. **Referenced table:** HistoricalDemandCategory (Nullable)	Reference	
Calendar	Defines current intervals for Order Fulfillment. Usually Month or Quarter. **Referenced table:** Calendar (Nullable)	Reference	
MaximumNumberOfCustomerChanges	The default number of customer-initiated changes allowed on a line item before certain application resources apply formatting to flag the order as having reached the maximum change threshold. When the maximum change threshold is reached, the order might typically require further investigation and/or being placed on hold pending resolution of the underlying customer issue. **Note:** If necessary, this change threshold can be specified for individual customers using the **MaximumNumberOfCustomerChanges** field on the **Customer** table.	Integer	
MaximumNumberOfSupplyChanges	The default number of supply changes allowed against any line item before certain application resources apply formatting to flag the order as having reached the maximum threshold. When the maximum change threshold is reached the order might typically require further investigation and/or being placed on hold pending resolution of the underlying supply issues. **Note:** If necessary, this change threshold can be specified for individual customers using the **MaximumNumberOfSupplyChanges** field on the **Customer** table.	Integer	

Table 7.33: OFConfiguration (Solutions) fields

Field name	Description	Data type	Key
RequestedStatus	A reference to the value in the **DemandStatus** table used to indicate a new customer request that has not yet been processed in RapidResponse. This should be a record with the **ProcessingRule** set to "Ignore". All new customer requests being brought into the Order Fulfillment application should reference this same **DemandStatus** value. **Referenced table:** DemandStatus (Nullable)	Reference	

OnHandType table

The **OnHandType** table is a control table that specifies whether the stock or inventory is considered in netting. In other words, this table specifies the rules for determining the availability of OnHand records in netting.

Table 7.34: OnHandType (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this OnHandType record. **Referenced table:** ControlSet	Reference	Yes
Description	A description of this type of OnHand. An explanation of the code in the Value field. **Default value**: blank string	String	
ProcessingRule	Specifies whether the stock is used in netting. Valid values are: • **Nettable** — considered in inventory netting calculations. • **NonNettable** — not considered in inventory netting calculations. **Default value**: Nettable	String (Enum)	
Value	The string value for this type of OnHand record. **Default value**: blank string	String	Yes
OnHands	Set of **OnHand** records that reference this OnHandType value.	Set	

OperationSequenceType table

The **OperationSequenceType** table contains processing rules applied to the name sequences of operations stored in the **OperationSequence** table. For example, it determines if a given sequence of

operations is the standard sequence in its routing or a parallel operation branching of the standard sequence.

Table 7.35: OperationSequenceType (Core) fields

Field name	Description	Data type	Key
AlignmentRule	When the duration of operations in a parallel sequence is different than the duration between the branch points in the standard sequence, this setting determined where those sequences are aligned. Valid values are: • **Earliest**—parallel sequences are aligned as early as possible. For example, if a parallel sequence is of shorter duration than the time between the branch and return operations in the standard sequence, the parallel sequence aligns with the start of the branch operation (with a float assumed at the end) • **Latest**—parallel sequences are aligned as late as possible. For example, if a parallel sequence is of shorter duration than the time between the branch and return operations in the standard sequence, the parallel sequence aligns with the end of the return operation (with a float assumed at the start). **Default value**: Earliest	String (Enum)	
ControlSet	The control set associated with this **OperationSequenceType** record. **Referenced table:** ControlSet	Reference	Yes
Description	An optional description of this operation sequence type.	String	
ProcessingRule	Specifies how a given operation sequence within a routing is processed. Valid values are: • **Ignore**—The operation sequence, and hence all of its operations, are ignored by the routing. • **Parallel**—The operation sequence is a parallel sequence that branches off the standard sequence in the routing. **OperationSequence** records that reference a type with this setting should have their **BranchOperation** and **ReturnOperation** fields populated to indicate the branching points from and to the standard sequence. • **Standard**—The operation sequence is treated as the standard sequence in the routing. Each routing should have one **OperationSequence** record referencing a type that uses this setting (all operations within a routing are ignored if it does not have a standard operation sequence). **Default value:** Ignore	String (Enum)	

Table 7.35: OperationSequenceType (Core) fields

Field name	Description	Data type	Key
Value	A unique identifier for this operation sequence type.	String	Yes
Operation Sequences	Set of **OperationSequence** records that reference this **OperationSequenceType** value.	Set	

OperationType table

This table controls the processing rules used for scheduling an operation.

Table 7.36: OperationType (Mfg) fields

Field name	Description	Data type	Key
BatchQuantityRule	When an operation has a batch quantity value of 0, this setting determines how it can process batched supplies received from the previous operation in the sequence. Valid values: • **IgnoreZero**—the operation can begin once it has received a single batch of supply from the previous operation in the sequence. • **UseZero**—the operation can begin only when the entire supply has been received from the previous operation in the sequence.	String (Enum)	
ControlSet	The control set associated with this OperationType record. **Referenced table:** ControlSet	Reference	Yes
DateRule	Specifies how date effectivity is to be applied. (DateRule is always applied, regardless of whether Model-Unit Effectivity or Pool have been enabled). Valid values are: • **AnchorDate**—tests the effective dates against the anchor date on the supply record. • **BlowThroughCalcDueDate**—tests the effective dates against the calculated due date on the supply record. Same as CalcDueDate. • **CalcDockDate**—tests the effective dates against the calculated dock date on the supply record. • **CalcDueDate**—tests the effective dates against the calculated due date on the supply record. • **CalcStartDate**—tests the effective dates against the supply record start date or calculated start date for planned loads • **Ignore**—ignores the effective dates (record treated as if effective from Past to Future) **Default value**: Ignore	String (Enum)	

Table 7.36: OperationType (Mfg) fields

Field name	Description	Data type	Key
DependentUnit Rule	This field supports Model and Unit- Effectivity. It defines how dependent load is to be handled with unit effectivity. Valid values are: • **Split**—split load according to the unit number range. Loads are not split if the supply's unit is less than zero. • **First**—calculate the entire load according to whether the supply StartUnit passes the unit range on the Bill record **Default value**: Split **Note:** If your company has not enabled Model-Unit Effectivity, this field is ignored.	String (Enum)	
Description	A description of this type of operation. An explanation of the code in the Value field. **Default value**: blank string	String	
EffectivityRule	Specifies how ranges of units and dates are to be interpreted when determining effectivity. This field applies to all effectivity rules (ranges apply to dates and unit ranges). Valid values are: • **InclusiveExclusive**— effective starting on start and ending before the end (recommended method). • **Never**— ignore this operation record regardless of all dates as well as Model and Unit-Effectivity rules. • **Always**— ignore all effectivity rules and treat the operation as active. • **Exclusive**— use effectivity dates and units if applicable (not effective on the dates or units). • **Inclusive**— effective from start to end inclusive. **Default value**: InclusiveExclusive	String (Enum)	

Table 7.36: OperationType (Mfg) fields

Field name	Description	Data type	Key
MUERule	This field supports, and is used to define application of, the Model and Unit-Effectivity analytics. Valid values are: • **Model**— the operation record is effective if the Model value on the operation record matches the Model on the Supply record • **Unit**— the operation record is effective if the StartUnit on the Supply record is in the range of the StartUnit and EndUnit from the operation record. DependentUnitRule and EffectivityRule are tested to determine whether the unit is in range. • **ModelUnit**— use both model and unit tests simultaneously. Model matches and the unit must be in range for the operation record to be effective. • **Ignore**— do not test model or unit for this operation record **Default value**: Ignore **Note:** If your company has not enabled Model-Unit Effectivity, MUERule is treated as Ignore.	String (Enum)	
TransitTime ProcessingRule	Valid values include: • **Hours** — interprets the TransitTime as the number of hours to move between operations • **Days** — interprets the TransitTime as the number of workdays it takes to move between operations without rounding (for example, moving from two hours into the day on operation 10 to operation 20 with one TransitTime Days, would move the time to two hours into the next workday). This rule should only be used with integer days and a fractional number will be rounded up to the next integer before calculating the transit time ending point. • **DaysRounding** — interprets the TransitTime as the number of workdays it takes to move between operations and start the next operation at the beginning of that day (for example, TransitTime would move ahead 1 day and if it is not at the beginning of the day, it will be moved to the beginning of the following workday). This rule should only be used with integer days and a fractional number will be rounded up to the next integer before calculating the transit time ending point. **Default value**: Hours	String (Enum)	

Table 7.36: OperationType (Mfg) fields

Field name	Description	Data type	Key
TransitTime SequenceRule	Controls whether to apply transit time before the queue time or after the wait time of the operation. Valid values are: • **BeforeOperation** — the time it takes to move from the previous operation to this operation • **AfterOperation** — the time it takes to move from this operation to the next operation. **Default value**: AfterOperation	String (Enum)	
Value	The string code for this type of operation. This is what will appear in the Operation records. **Default value**: blank string	String	Yes
CRPOperations	Set of **CRPOperation** records that reference this OperationType value.	Set	
Operations	Set of **Operation** records that reference this OperationType value.	Set	

OrderPolicy table

The **OrderPolicy** table is a control table that specifies the rules for determining the size and dates for placing orders. The start date is the next higher integer number of days from FixedLeadTime + (VarLeadTime * Quantity).

Table 7.37: OrderPolicy (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this OrderPolicy record. **Referenced table:** ControlSet	Reference	Yes
Description	A description of the OrderPolicy. **Default value**: blank string	String	

Table 7.37: OrderPolicy (Mfg) fields

Field name	Description	Data type	Key
LotSizeLastOrder	Specifies, for each order policy, whether to apply lot-sizing rules to the last planned order in the horizon. Lot-sizing rules include minimum order quantities (PartSource.MinimumQty), maximum order quantities (PartSource.MaximumQty), and multiple order quantities (PartSource.MultipleQty). Valid values are: • **Y**—applicable lot sizing rules are applied to the last planned order as they are applied to any other planned order. • **N**—lot-sizing rules are not applied to the last planned order. Only the quantity required is ordered; that is, the **PlannedOrder.NeedQty** and **PlannedOrder.Quantity** fields are the same. **Default value:** Y	Boolean	

Table 7.37: OrderPolicy (Mfg) fields

Field name	Description	Data type	Key
MaximumUsage	Specifies how the maximum order size, if any, is determined for each part source using this policy. Valid values are: • **Average**—if the required quantity exceeds **PartSource.MaximumQty**, use the **MaximumQty** to determine the number of planned orders to generate, and then average the required quantity across these orders. This option allows a given requirement to just be covered, respecting any Min, Max, or Mult policies, without bringing any supply in earlier than necessary. In order to use this option, a given requirement must have exactly one part source that can satisfy it, and the value of **PartSource.TakTime** for that source must be set to 0. If these conditions are not met, this option is equivalent to the "Use" option. • **CampaignPlanning**—each planned order created is for the exact quantity (batch size) that is specified in PartSource.MultipleQty. This setting plans supplies in production campaigns with the minimum and maximum quantities allowed per campaign then determined by the MinimumQty and MaximumQty fields on the PartSource record. Therefore, the minimum number of batches per campaign is calculated as `MinimumQty/MultipleQty`, while the maximum number of batches per campaign is calculated as `MaximumQty/MultipleQty`. Additionally, if the part source is constrained, then all batches in a given campaign must be scheduled through a contiguous block of the constraint. This option supports the optional Campaign Planning capability. • **Ignore**—do not use **PartSource.MaximumQty** value in determining planned order quantities. • **Kanban**—each planned order created for the part source is for the quantity defined by **SourceKanban.BinQty** (the current approved bin quantity). As well, the total supply of the associated part must not exceed the value of **SourceKanban.BinQty** * **SourceKanban.Bins** (the current number of bins in the system). When this setting is used, the values of **PartSource.MultipleQty, PartSource.MinimumQty**, **PartSource.MaximumQty** are all ignored. Also, if a part source using this setting has no corresponding entries in the **SourceKanban** table, then both **BinQty** and **Bins** are treated as zero and no planned orders are generated against the source. • **OverRideDaysSupply**—cover at least one day's requirements. Will not cover days of supply if the quantity would exceed maximum. (Note: this value is obsolete and is treated the same as "Use".) • **Use**—use the value in the **PartSource.MaximumQty** in determining the **PlannedOrder.Quantity**. The planned	String (Enum)	

Table 7.37: OrderPolicy (Mfg) fields

Field name	Description	Data type	Key
	orders that are generated will be less than or equal to the applicable **PartSource.MaximumQty** (may be more than one applicable part source) based on the required demand. It's possible that there could be more than one planned order for the same part source on the same day if the amount needed exceeds **PartSource.MaximumQty** (either the demand that is being satisfied or the demands if **Part.NumberofDaysSupply** is also used). **Note:** A global setting limiting the number of planned orders per day can result in orders that exceed **PartSource.MaximumQty**. For more information, see "Limiting the number of planned orders" on page 2204. **Default value:** Ignore		
MinimumUsage	Specifies the minimum usage setting for each order policy: • **Ignore**—do not use the **PartSource.MinimumQty** value in determining the **PlannedOrder.Quantity**. • **Use**—use the value in the **PartSource.MinimumQty** in determining the **PlannedOrder.Quantity**. The planned orders that are generated will be greater than or equal to the applicable **PartSource.MinimumQty** (there might be more than one applicable PartSource) based on the required demand. • **RoundMult**—use the value in the **PartSource.MinimumQty** rounded up to the value in the **PartSource.MultipleQty** in determining the **PlannedOrder.Quantity**. The PlannedOrders that are generated will be greater than the applicable **PartSource.MinimumQty** (there might be more than one applicable PartSource) but rounded to a multiple of the **PartSource.MultipleQty**. **Default value:** Use	String (Enum)	

Table 7.37: OrderPolicy (Mfg) fields

Field name	Description	Data type	Key
MultipleUsage	Specifies the multiple usage setting for each order policy: • **Ignore**—do not use the **PartSource.MultipleQty** value in determining planned order quantities. • **Use**—use the value in the **PartSource.MultipleQty** in determining the **PlannedOrder.Quantity**. The planned orders that are generated will have a quantity that is in increments (multiples) of the applicable **PartSource.MultipleQty** (there might be more than one applicable part source) based on the required demand quantity. • **Units**—the value in **PartSource.MultipleQty** is ignored and treated as if it was set to "1". As necessary, order quantities are rounded up to the next whole number (intended to ensure supply is not planned in fractional quantities). **Default value:** Use **Note:** If **MaximumUsage** is set to either "Kanban" or "CampaignPlanning", then this setting is ignored and planned orders are always set to the effective bin or batch size, respectively.	String (Enum)	
OrderGeneration Rule	Controls how RapidResponse generates planned orders. Valid values are: • **NoOrders**—do not generate planned orders • **AnyTime**—generate planned orders whenever demand requires it (including the past) • **AfterRunDate**—generate planned orders but only after **Part.PlanningCalendars.RunDate.FirstDate** • **AfterPTF**—generate planned orders but only on or after **PartSource.PTFDate**. Note that the calculation of **PTFDate** is affected by the setting in the **PTFRule** field. **Default value:** AnyTime	String (Enum)	

Table 7.37: OrderPolicy (Mfg) fields

Field name	Description	Data type	Key

PTFRule	Specifies how the planning time fence date (**PartSource.PTFDate**) is calculated for part sources that use this order policy.
	Typically, the planning time fence might be set to a part's lead time or to a specified number of work days. If the **OrderGenerationRule** is set to "AfterPTF", the calculated **PTFDate** then represents the earliest date on which a new planned order from the part source is allowed to be due.
	Valid values are:
	• **Fence**—The **PTFDate** is determined by adding the **Part.PlanningTimeFence** value to **RunDate**.
	Note also that the **PTFUnit** setting affects this calculation as follows:
	  • If **PTFUnit** is set to "Part" then **PartSource.PTFDate** is calculated as (Part.PlanningCalendars.RunDate.FirstDate + PlanningTimeFence expressed in Part.PlanningCalendars.TimeUnits).
	  • IF **PTFUnit** is set to "Source" then **PartSource.PTFDate** is calculated as (Part.PlanningCalendars.RunDate.FirstDate + PlanningTimeFence expressed in Source.LeadTimeUnit), converted to Part.PlanningCalendards.TimeUnits date.
	• **LastDueFence**—the **PartSource.PTFDate** is calculated as the latest of either the **Fence** calculation (described above) or the **DueDate** of the last scheduled receipt or supply allocation assigned to the part source (expressed in **Part.PlanningCalendars.TimeUnits)**. This setting is similar to "LastDueFenceAll" but only considers the current part source.
	• **LastDueFenceAll**—the **PartSource.PTFDate** is calculated as the latest of either the **Fence** calculation (described above) or the **DueDate** of the last scheduled receipt or supply allocation assigned to any part source that provides the part (expressed in **Part.PlanningCalendars.TimeUnits)**. This setting is similar to "LastDueFence" but might be used when have the planning time fence synchronized across all of a part's sources is important.
	• **LastDueLead**—the **PTFDate** is calculated as the latest of either the **Lead** calculation (described below) or the **DueDate** of the last scheduled receipt or supply allocation assigned to the part source (expressed in **Part.PlanningCalendars.TimeUnits**). This setting is similar to "LastDueLeadAll" but only considers the current part source.
	• **LastDueLeadAll**—the **PTFDate** is calculated as the latest of either the **Lead** calculation (described below) or the
		String (Enum)	

Table 7.37: OrderPolicy (Mfg) fields

Field name	Description	Data type	Key
	DueDate of the last scheduled receipt or supply allocation assigned to any part source that provides the part (expressed in **Part.PlanningCalendars.TimeUnits**). This setting is similar to "LastDueFence" but might be used when have the planning time fence syncrhoznied across all of a part's sources is important. • **Lead**—The **PTFDate** is determined by adding both the part's lead time and **Part.PlanningTimeFence** value to **RunDate**. Thus, if the planning time fence should represent lead time only, ensure to leave **PlanningTimeFence** set to 0. Note also that the **PTFUnit** setting affects this calculation as follows: • If **PTFUnit** is set to 'Part' then **PartSource.PTFDate** is calculated as (Part.PlanningCalendars.RunDate.FirstDate as a start date, converted to a due date) + PartSource.PlanningTimeFence expressed in Part.PlanningCalendars.TimeUnits. • If **PTFUnit** is set to 'Source' then **PTFDate** is calculated as (Part.PlanningCalendars.RunDate.FirstDate + PlanningTimeFence expressed in Source.LeadTimeUnit) as a start date converted to a due date. **Default value:** Fence **Note:** With any of the "LastDue" options, supplies can be included or excluded from the **PTFDate** calculation by using the **PTFLastDueRule** setting on the SupplyType, SupplyStatus, and SupplyAllocationType tables. By default, all scheduled receipts and supply allocations are included. **Note:** This field was modified in Service Update G1908.		

Table 7.37: OrderPolicy (Mfg) fields

Field name	Description	Data type	Key
PTFUnit	Affects calculations performed by settings in the **PTFRule** field when **Source.LeadTimeUnit, Source.ShipCalendar**, and **Part.PlanningCalendars.TimeUnits** do not all refer to the same Calendar (for example, this is often the case with "transfer" part sources). In such cases, this setting determines the time unit calendar (part or source's time units) to be used when calculating **PartSource.PTFDate**. Valid values are: • **Part**—Use when the planning time fence should be in the part's time units (**Part.PlanningCalendars.TimeUnits**), and applied after lead time when **PTFRule** is either "Lead", LastDueLead, or "LastDueLeadAll". • **Source**—Use when the planning time fence should be in the source's time units (**PartSource.Source.LeadTimeUnit**), and applied before lead time when **PTFRule** is either "Lead", "LastDueLead", or "LastDueLeadAll". **Default value**: Source	String (Enum)	
UseFixedLeadTime	Specifies for each order policy whether to consider the fixed lead time during MRP processing. Valid values are: • **Y**—the **PartSource.FixedLeadTime** is used in the calculation of **ScheduledReceipt.CalcStartDate**, **PlannedOrder.StartDate**, or both. • **N**—the **PartSource.FixedLeadTime** is not used in the calculation of **ScheduledReceipt.CalcStartDate**, **PlannedOrder.StartDate**, or both. **Default value**: N	Boolean	

Table 7.37: OrderPolicy (Mfg) fields

Field name	Description	Data type	Key
UseVarLeadTime	Specifies for each order policy whether to enable variable lead time during Netting calculations. Variable lead time is dependent on order quantity and used in calculating the start date on supplies (**ScheduledReceipt.CalcStartDate** or **PlannedOrder.StartDate**). Depending on the option selected in this field, variable lead time can be calculated based on a factor provided on the part source, set to the calculated time needed to run the order through all operations in its routing, or ignored altogether. Valid values are: • **CRP**—Variable lead time is enabled for supplies from this part source. To determine this portion of lead time, the time needed to run the supply through all work center operations in its routing is used. This can include float times specified in the **PartSource.CRPFloatBefore** and/or **PartSource.CRPFloatAfter** fields. Note that if the **SupplyType.CapacityProcessingRule** setting applicable to the supply is "Ignore", then this option is treated the same as "N". For more information about variable lead time based on work center capacity, see "Operations and supply lead time" on page 1532. • **N**—Variable lead time is ignored for supplies using this part source. • **Y**—Variable lead time is enabled for supplies from this part source. To determine this portion of lead time, **PartSource.VarLeadTime** is multiplied by either **PlannedOrder.Quantity** or **ScheduledReceipt.Quantity**. **Default value**: N	String (Enum)	
Value	The string code for this OrderPolicy. This is what will appear in the part record. **Default value**: blank string	String	Yes
YieldRounding Usage	Specifies whether decimal place rounding is applied to effective planned order and scheduled receipt quantities. Rounding can reduce or eliminate fractional amounts on effective supply quantities after applying yield. Valid values are: • **Ignore**—no rounding is applied to the effective quantities that remain on scheduled receipts and planned orders after applying yield. • **Use**—effective quantities on scheduled receipts and planned orders are rounded down after applying yield. Rounding is to the number of decimal places specified in the **Part.UnitOfMeasure.RoundingPrecision** field. **Default value**: Ignore	String (Enum)	

Table 7.37: OrderPolicy (Mfg) fields

Field name	Description	Data type	Key
YieldUsage	Specifies how to interpret yield values at the part level. This setting is applied against the **PartSource.Yield** field (to account for scrap) and the **PartSource.CoProductYield** (to account for co-product and by-product supply). For planned orders, yield is applied against the quantity required by the demand to return the **PlannedOrder.Quantity** (the amount required in consideration of yield, with the net amount received into inventory reported in **PlannedOrder.EffQuantity**. For scheduled receipts, yield is applied against **ScheduledReceipt.Quantity** to return the **ScheduledReceipt.EffQuantity**. For more information, see "Yield expressions for planned orders and scheduled receipts" on page 1393. Valid values are: • **Ignore**—do not use the Yield factor. It ignores the **Yield** and **CoProductYield** fields on the PartSource (even if populated) and the yield is always assumed to be 1 (no loss). • **YieldFraction**—value from 0 through 1 (1 means no loss). • **YieldPercent**—value from 0 through 100 (100 means no loss). • **ScrapFraction**—value from 0 through 1 (0 means no loss). • **ScrapPercent**—value from 0 through 100 (0 means no loss). • **ScrapPiece**—allows a fixed quantity per order to be scrapped. • **InflationFraction**—indicates amount to inflate supply using formula *1 / (1 + PartSource.Yield)* • **InflationPercent**—indicates amount to inflate supply using formula *1 / (1 + PartSource.Yield * 0.01)* **Default value**: YieldFraction set to 1 **Note:** The CoProductYield field only uses the YieldFraction, YieldPercent, and Ignore values. It treats InflationPercent, ScrapPiece, and ScrapFraction, as YieldFraction, and treats ScrapPercent and InflationPercent as YieldPercent.	String (Enum)	
PartSources	Set of **PartSource** records that reference this OrderPolicy value.	Set	

OrderPriority table

The **OrderPriority** table contains values that can be used to prioritize the order in which demands are satisfied or to prioritize the order in which supplies are consumed. The priority associated with each record in the **OrderPriority** table is defined through its **PlanningPriority** field. Together **OrderPriority** and **TransactionSequence** (found on the **IndependentDemand** and **ScheduledReceipt** tables) operate together to provide an unlimited number of levels of priority. That is, demands having the same

planning priority and due date are then sorted by TransactionSequence. Note that TransactionSequence is only considered if the value of the **MaintainCommitments** field is set to Y. For information about order priority, see "Order priority calculations" on page 1765.

This table is editable, therefore records can be added and modified.

Table 7.38: OrderPriority (Mfg) fields

Field name	Description	Data type	Key
AllocationRule	Specifies how supplies are allocated to demands within a given order priority. Valid values are: • **FirstComeFirstServed**—Supplies are allocated to demands based on priority and due date. • **FairShare**—If **PartType.SupplyAllocationRule** is set to 'ByAvailable', supplies are allocated to demands within one **PlanningCalendars.AllocationCalendar** interval based on demand size, with larger demands receiving more of the earliest available supply. • **EqualShare**—If **PartType.SupplyAllocationRule** is set to 'ByAvailable', supplies are allocated to demands within one **PlanningCalendars.AllocationCalendar** interval based on the number of orders, with each demand receiving the same amount of the earliest available supply. **Default value**: FirstComeFirstServed **Note:** The "FairShare" and "EqualShare" options can subsequently be turned off, or limited within a specific date horizon, at the part-level. This can be set using the **PartType.SupplyShareRule** field. For example, parts at one level in the product structure might require limited supplies to be shared amongst High priority demands, while parts at another level in the product structure might not need supplies shared amongst their High priority demands.	String (Enum)	
ControlSet	The control set associated with this OrderPriority record. **Referenced table:** Core::ControlSet	Reference	Yes
Constraint Allocation Calendar	Reference to a calendar defining the period over which demands for parts that share a common constraint through their part source(s), and belong to the same priority level, are collected together for the purpose of sharing potentially limited constraint availability between those part sources. For example, if set to a weekly calendar, then eligible demand due in a given week are collected together and, and if there is an insufficient amount of a shared constraint, the available amount of that constraint is shared between part sources based on the quantities of the demands being satisfied. Used only if **ConstraintAllocationRule** is set to "FairShare". **Referenced table:** Calendar (nullable)	Reference	

Table 7.38: OrderPriority (Mfg) fields

Field name	Description	Data type	Key
Constraint AllocationRule	Indicates whether any limited constraint availability is to be shared fairly between different part sources that might require it to satisfy demands in each period as defined by **ConstraintAllocationCalendar** (for example, workday or week). Valid values are: • **FairShare**—Demands of a given priority level that share a common constraint through their part source(s) are processed together within each **ConstraintAllocationCalendar** period. If there is limited constraint available within the period, then it shared between part sources based on the quantity of the demand(s) being satisfied by each. Note that at the individual part-level, the fair-sharing of constraints can be either disabled or limited to a specific time horizon, using the **PartType.ConstraintShareRule** setting. • **FirstComeFirstServed**—Demands are processed one by one. If there is limited constraint available it is allocated based on a sequence of factors including priority, due date, part name. This setting corresponds to how constraint calculations were always performed in versions prior to 11.2. **Default value**: FirstComeFirstServed **Note:** For more information, see "FairShareAllocation" on page 1679.	String (Enum)	
Description	A description for this order priority.	String	
IntendedDriver Type	Specifies the types of orders that are expected to use this priority. It is used by some RapidResponse legacy applications; not directly used by RapidResponse calculations. Valid values are: • ScheduledReceipt • IndependentDemand (default) • SafetyStock	String (Enum)	

Table 7.38: OrderPriority (Mfg) fields

Field name	Description	Data type	Key
Maintain Commitments	Specifies whether the transaction sequence is considered part of priority such that due dates on existing orders are maintained when new orders are dropped in. Values are: • **Y**—transaction sequence is considered part of priority. Typically, this setting should be used for orders that are truly committed to production (for example, the highest priority independent demands). • **N**—transaction sequence is not considered part of priority. This is the default value, and should be used for most priorities. If the **PartType.CommitLevel** field is set to Low, transaction sequence is ignored regardless of the setting on this field. **Caution:** More memory is consumed when orders have **MaintainCommitments** set to "Y". Therefore, as noted above, this setting should be limited to only those orders that are truly committed to production.	String (Enum)	

Table 7.38: OrderPriority (Mfg) fields

Field name	Description	Data type	Key
MLSAllocation Rule	This setting controls how demands of a given priority level are processed in Netting when multi-level search logic is enabled. When there is insufficient material or constraint to cover all demands configured for "partial planning", this setting determines whether shortages throughout the product structure will be fairly shared between driver demands for a given period and priority level. Valid values are: • **FirstComeFirstServed**—Demands of a given priority level are processed individually and in due date order. This setting corresponds to how multi-level search logic always worked prior to Version 2016.2, Service Update 10. When demands of a given priority have to be left unsatisfied due to partial planning logic, then the shortages will tend to be unevenly distributed (limited material and/or constraint will go to demands that are processed first). • **Fairshare**—Within each allocation interval, demands of each priority level are broken up and processed iteratively. After demands are broken into defined increments, Netting then processes a defined portion of each demand before looping through the incremental demand portions again and this process continues until all demands have been fully processed. When multi-level search is used together with partial planning logic, this fair-sharing of constraints or material can help ensure that if some demand within a given period and priority level has to be left unsatisfied, then those shortages will be fairly distributed within each period. With this setting, the **MLSFairShareCalendar** and **MLSFairSliceFactor** fields define how demands are broken up for iterative processing. **Default value:** FirstComeFirstServed **Note:** This field was added in Version 2016.2, Service Update 10. Demands for parts where **PartType.CommitLevel** is set to "Medium" or "Low" are always processed as if this field were set to "FirstComeFirstServed".	String (Enum)	

Table 7.38: OrderPriority (Mfg) fields

Field name	Description	Data type	Key
MLSFairshare Calendar	A reference to the calendar used to define the period over which demands of a given priority level are processed together in multi-level search logic. For example, all demands due in each Week might be processed together and any shortages fairly shared between those weekly demands. If this reference is left Null, then an Everyday calendar is used. **Referenced table:** Calendar (Nullable) **Note:** This field was added in Version 2016.2, Service Update 10, and only applies when the **MLSAllocationRule** field is set to "Fairshare".	Reference	
MLSFairshare SliceFactor	Specifies the number of incremental portions into which demands of a given priority level are split for processing by multi-level search logic. For example, if is set to "4", then a demand for 80 would be split and processed in four separate increments of 20 units. The value specified in this field should be between 1 and 10. Any value less than 1 is treated as 1 (demands are processed in whole), and any value greater than 10 is treated as 10 (at least 10% of each demand must be processed at a time). Note also that any splits for multi-level fair share logic will be rounded down to respect the part's **AllocationMultiple** setting. **Default value:** 1 **Note:** This field was added in Version 2016.2, Service Update 10, and only applies when the **MLSAllocationRule** field is set to "FairShare".	Integer	
Optimization Priority	Priority used by certain legacy applications in calculating customer service objective. High values indicate high logical priorities, and relative values are considered significant. For example, orders with an optimization priority of 10 are twice as important as those with an optimization priority of 5. Zero effectively excludes independent demands with this order priority form the customer service optimization objective. **Default value**: 0 **Note:** This field is obsolete.	Quantity	

Table 7.38: OrderPriority (Mfg) fields

Field name	Description	Data type	Key
PeriodEffective	Specifies whether this type of priority is dependent on the period the demand occurs in. Valid values are: • **Y**—the priority value is period dependent. Within the current period, as defined by Part.PlanningCalendars.AllocationCalendar, demand priorities are taken from the PlanningPriority field. However, any unsatisfied demands from this interval are assigned a higher priority than demands in subsequent periods regardless of their PlanningPriority value. This setting can be used to try and ensure older past due demands are satisfied before demands in the current period. • **N**—the priority value is not period dependent. Demand priorities are always taken from the PlanningPriority field regardless of the period in which the demand occurs. **Default value:** N **Note:** For more information, see "Period effective priority" on page 1768.	Boolean	
PlanningPriority	The relative importance associated with each OrderPriority value. Lower values are considered the higher effective priority. Different OrderPriority records can share the same PlanningPriority value. If multiple orders share the same PlanningPriority value, they are treated the same, even if their OrderPriority differs. Therefore, it is recommended that you give each OrderPriority record a distinct PlanningPriority value.	Integer	
SchedulePriority	The constraint scheduling priority for supplies associated with this OrderPriority value (where lower values are considered the higher effective priority). SchedulePriority can be used to ensure high-priority supplies consume constraint as close to the due date as possible. If constraint availability then forces some supplies to be pre-planned, lower priority supplies are pre-planned earlier (and therefore held in inventory longer than higher priority supplies). This is useful in cases where high priority supplies are also higher value supplies. For more information on this field and considerations around its usage, see "SchedulePriority" on page 1659. **Default value**: 0	Integer	

Table 7.38: OrderPriority (Mfg) fields

Field name	Description	Data type	Key
TwoDate PlanningRule	Specifies how demands of this priority are used in two-date planning logic. Typically, the capable-to-promise analytic allots supplies to demands to try and satisfy the date on which order shipment has been committed to the customer (**IndependentDemand.DueDate**). When two-date planning is enabled, after first planning to the due date, RapidResponse will try to move demand availability towards the original date on which the customer requested shipment of the order (**IndependentDemand.RequestDate**). Note that such improvements in demand availability are only made if they do not adversely affect the available date on other demands (unless those other demands belong to a lower priority level with a setting of "Ignore" in this field). For more information about two-date planning logic, see "Two-date planning" on page 1803. Valid values are: • **Ignore**—Two-date planning is not enabled for this priority. Demands of this priority level are only planned to try and satisfy their due date. Additionally, these demands might have their available dates adversely impacted by attempts to meet the request date on higher priority demands that are enabled for two-date planning. • **Protect**—Two-date planning is not enabled for this priority. Demands of this priority level are only planned to try and satisfy their due date. However, these demands are protected and will never have their availabilities made worse by attempts to meet the request date on higher priority demands enabled for two-date planning. • **Use**—Two-date planning is enabled for this priority. Demands of this priority level are first planned to their due date (less applicable safety lead time) by Netting logic. CTP calculations then initially try to satisfy that same date, before a second pass ultimately attempt to move the demand closer to the original customer request date (if possible). In order to try and achieve their RequestDate, these demands might adversely impact the available date of lower-priority demands that use the "Ignore" setting. • **UseWithHardSafetyLeadTime**—Two-date planning logic is enabled for this priority, and request dates are adjusted for safety lead time. Netting logic will plan to cover demands of this priority at the demand due date less safety lead time for the part. Capable-to-promise logic will initially try to satisfy the demand at its due date less safety lead time, and in a second pass will then	Reference	

Table 7.38: OrderPriority (Mfg) fields

Field name	Description	Data type	Key
	try to satisfy the demand at its request date less safety lead time if this can be done without making other demands worse off (other than lower priority demands that use the "Ignore" setting in this field). Note though that within a given planning priority, demands that use this setting are processed before demands that use the "UseWithSoftSafetyLeadTime" setting. Thus, a demand with this setting might have its safety-lead time adjusted demand date satisfied even if it makes a "UseWithSoftSafetyLeadTime" demand late for its (non-adjusted) demand date. • **UseWithSoftSafetyLeadTime**—Two-date planning logic is enabled for this priority, and request dates are adjusted for safety lead time. Netting logic will plan to cover demands of this priority at the demand due date (does not apply safety lead time). Capable-to-promise logic will initially also try to satisfy the demand at that same due date, and in a second pass will then try to move the demand availability closer to its request date less safety lead time if this can be done without making other demands worse off (other than lower priority demands that use the "Ignore" setting in this field). **Default value**: Ignore **Note:** Ensure that supplies and part sources satisfying demands enabled for two-date planning have their **SupplyStatus.AvailableDateLimit** field set to "CalcRequestStartDate". This includes both supplies for the end-item itself as well as any component supplies needed to build the end-item. The "CalcRequestStartDate" setting ensures that supplies can be built early enough to satisfy the original customer request date. **Note:** Parts that have demands enabled for two-date planning should typically use a **PartType.ATPCTPRule** setting of "Latest" in order to allow pulling supplies in to the request date while reducing inventory carrying cost. If using the default **ATPCTPRule** of "Earliest", then results might not be as expected since this setting will try to ensure demands are satisfied with later supplies (assuming it doesn't impact the ability to satisfy the demand on time). This can leave earlier supply as excess rather than using it to try and meet customer request dates. **Note:** If demands of priorities using either the "UseWithSoftSafetyLeadTime" or "UseWithHardSafetyLeadTime" setting do not have a RequestDate populated, then CTP logic will ultimately try to satisfy the demands at their due date less safety lead time instead.		

Table 7.38: OrderPriority (Mfg) fields

Field name	Description	Data type	Key
	Note: This field was modified in Version 2016.2, Service Update 6.		
TwoDatePriority Limit	A calculated field reporting the highest **PlanningPriority** value found on any **OrderPriority** record, in a given control set, where the **TwoDatePlanningRule** setting is either "Use" or "Protect". This represents the lowest priority level whose demands are either enabled for, or protected against, two-date planning logic. Demands at priority levels below this one might be subject to having their available dates adversely impacted when two-date planning logic attempts to meet the request date on higher priority demands. Note also that if a record has a lower **PlanningPriority** (higher priority) than the value reported this field and has a **TwoDatePlanningRule** of "Ignore", it will be treated as if it were set to "Protect" instead.	Integer	
Value	The string value for this type of order priority.	String	Yes
DemandTypes	Set of **DemandType** records that reference this OrderPriority value.	Set

OutlierType table

The **OutlierType** table contains rules used in the detection of outliers in historical data for items configured for statistical forecasting and for inventory planning and optimization. Before an item's statistical forecast is generated or before an item's safety stock recommendations are calculated, rules in this table determine how outliers in historical data are identified as well as how to adjust any outliers that are detected.

For more information about using this field in the statistical forecasting process, see "Define outlier handling" on page 2022.

This table was modified in Version 2016.2, Service Update 5, to support the Inventory Planning and Optimization application. For more information about its usage in the safety stock configuration process, see "Safety stock item outlier processing" on page 1983.

Table 7.39: OutlierType (Mfg) fields

Field name	Description	Data type	Key
AboveThresholdRule	If an outlier is detected above the upper threshold, this rule specifies the type of adjustment made to reduce the historical actual quantity. The selected option determines the value used in place of the outlier quantity. Valid values are: • **Forecast**—For statistical forecasting only, the item's calculated value from **StatisticalForecastOutlier.Forecast** is generally used. The calculation of **Forecast** depends on the **DataRule** setting in this table as follows. If using the "MovingAverageError" setting, then the moving average up to the point where the outlier occurs is used. If using the optional "RstlError" setting, then the sum of the trend and seasonal components is used. If using the "Historical" setting, then **Forecast** returns -1 and the mean is used instead. • **Ignore**—the item's historical actual quantities are left as is without any outlier adjustments. • **Mean**—the item's average quantity across the historical demand actual periods is used. • **Median**—the item's median quantity across the historical demand actual periods is used. • **SmoothKeepExcess**—the item's outliers quantities are adjusted by using parameters defined on the item to smooth the quantity above the outlier threshold over a number of intervals backward and then forward. If, after smoothing, any excess remains above the outlier threshold, it is left as is. • **SmoothRemoveExcess**—the item's outlier quantities are adjusted by using parameters defined on the item to smooth the quantity above the threshold over a number of intervals backward and then forward. If, after smoothing, any excess remains above the outlier threshold, that excess is reduced to the demand outlier threshold for the item. • **Threshold**—the item's upper threshold is used (quantity is decreased exactly to the point where it is no longer considered an outlier). **Default value:** Threshold **Note:** For more information about how the selected smoothing options are applied, see "Processing outliers" on page 2025 for statistical forecasting or "Processing outliers" on page 1987 for safety stock items. **Note:** The Ignore, SmoothKeepExcess, and SmoothRemoveExcess enumeration values were added in Version 2016.2, Service Update 5.	String (Enum)	

Table 7.39: OutlierType (Mfg) fields

Field name	Description	Data type	Key
BelowThreshold Rule	If an outlier is detected below the lower threshold, this rule specifies the type of adjustment made to increase the historical actual quantity. The selected option determines the value used in place of the outlier quantity. Valid values are: • **Forecast**—For statistical forecasting only, the item's calculated value from **StatisticalForecastOutlier.Forecast** is generally used. The calculation of **Forecast** depends on the **DataRule** setting in this table as follows. If using the "MovingAverageError" setting, then the moving average up to the point where the outlier occurs is used. If using the optional "RstlError" setting, then the sum of the trend and seasonal components is used. If using the "Historical" setting, then **Forecast** returns -1 and the mean is used instead. • **Ignore**—the item's historical actual quantities are left as is without any outlier adjustments. • **Mean**—the item's average quantity across the historical demand actual periods is used. • **Median**—the item's median quantity across the historical demand actual periods is used. • **SmoothKeepExcess**—the item's outliers quantities are adjusted by using parameters defined on the item to smooth the quantity below the outlier threshold over a number of intervals backward and then forward. If, after smoothing, any excess remains below the outlier threshold, it is left as is. • **SmoothRemoveExcess**—the item's outlier quantities are adjusted by using parameters defined on the item to smooth the quantity below the threshold over a number of intervals backward and then forward. If, after smoothing, any excess remains below the outlier threshold, that excess is reduced to the demand outlier threshold for the item. • **Threshold**—the item's lower threshold is used (quantity is increased exactly to the point where it is no longer considered an outlier). **Default value:** Threshold **Note:** For more information about how the selected smoothing options are applied, see "Processing outliers" on page 2025 for statistical forecasting or "Processing outliers" on page 1987 for safety stock items.	String (Enum)	

Table 7.39: OutlierType (Mfg) fields

Field name	Description	Data type	Key
DataRule	A rule that determines the specific data used for outlier detection for an item. Valid values are: • **Historical**—the actual and unaltered historical data points are used in calculating outliers. • **MovingAverageError**—differences between the actual historical data points and the moving average is used. The moving average is calculated over a number of intervals as set by the **OutlierMovingAverageWindow** field on the **ForecastItemParameters** table (for statistical forecasting) and the **MovingAverageWindow** field on the **SafetyStockItem** table (for inventory planning and optimization). • **RstlError**—adjusted actuals, after removal of any seasonal and trend components, are used. This option is available only with the optional Rforecast capability and uses the stl function in the R statistical programming language. **Default value:** Historical	String (Enum)	
Description	An optional description of this type.	String	

Table 7.39: OutlierType (Mfg) fields

Field name	Description	Data type	Key
DetectionRule	A rule that determines the method for detecting outliers in an item's historical data. Note that most settings in this field rely on the **ForecastItemParameters.OutlierThreshold** field (for statistical forecasting) and the **SafetyStockItem.DemandOutlierThreshold** (for inventory planning and optimization) as input into outlier detection. For example, it might indicate the number of standard deviations away from the mean where a value is considered an outlier. Valid values are: • **IglewiczHoaglinMethod**—Uses a modified z-score to measure distance from the mean. A point is considered an outlier if it is outside the following range $[0.6745 * \mid (x_i - Md)/(MdAD)\mid] \geq Zscore$ then the data value x_i is an outlier. Where *Md* is the median, *MdAD* is the median absolute deviation, and is x_i the data value. • **Rtsclean**—Uses loess with non-seasonal data and a periodic stl decomposition with seasonal data to identify and detect outliers. When using this option, the **DataRule** setting is always treated as if it were set to "Historical" (actual historical data without decomposition must be used). Also, this option is available only with the optional Rforecast capability and uses the tsclean method in the R statistical programming language. • **StandardDeviation**—Assumes a normal distribution of data. Outliers are then identified as those points that are a specified number of standard deviations above or below the mean. For example, if **OutlierThreshold** is set to "3", then points more than three standard deviations away from the mean are outliers. • **Winsorizing**—Data is sorted by quantity and outliers are identified as those points that are outside a specified percentile in the ordered data. For example, if **OutlierThreshold** is ".05", then points below the 5th percentile and above the 95th percentile in the data are considered outliers. **Default value:** StandardDeviation	String (Enum)	
Value	A unique string identifier for this control setting.	String	Yes
ForecastItem Parameters	Set of **ForecastItemParameters** records that reference this **OutlierType** value.	Set	
SafetyStockItems	Set of **SafetyStockItem** records that reference this **OutlierType** value.	Set	

PartSourceType table

The **PartSourceType** table is a control table used to define the characteristics of each potential supply source (for example, Make, Buy, and Transfer). This table is referenced from the **PartSource** table.

Table 7.40: PartSourceType (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this PartSourceType record. **Referenced table:** ControlSet	Reference	Yes
Constraint DateRule	Specifies how constraint is applied and planned orders generated for this part source. Valid values are: • **Start**—the Constraint is applied at StartDate (the date when processing of the order starts), and a separate planned order created for each constraint period. If there is not enough constraint in a given period, then a new (earlier) planned order is created with a new DueDate based on that (earlier) start date. For part sources constrained by a fixed constraint, this value is treated the same as StartExtend (only one planned order is created). • **Ship**—the Constraint is applied at ShipDate (the date when the order is to be shipped), and a separate planned order created for each constraint period. If there is not enough constraint in a given period, then a new (earlier) planned order is created with a new DueDate based on that (earlier) start date. For part sources constrained by a fixed constraint, this value is treated the same as ShipExtend (only one planned order is created). Note that when a scheduled receipt references a **SupplyStatus.IgnoreStartDate** of "N", then constraint is applied at order **StartDate** plus lead time (which might not neccesarily equate to the **ShipDate**). • **DuringLeadTime**—the Constraint is applied between ShipDate and StartDate, and one planned order is created with StartDate extended if there is not enough constraint available within lead time (that is, between StartDate and ShipDate.) • **StartExtend**—the Constraint is applied at StartDate, and one planned order is created with StartDate extended if additional constraint periods are required. • **ShipExtend**—the Constraint is applied at ShipDate, and one planned order is created with ShipDate extended if additional constraint periods are required. **Default value**: Ship **Note:** If this field is set to "DuringLeadTime", "Start", or "StartExtend", then **PartSource.VarLeadTime** is always ignored. For more information about ConstraintDateRule, see "ConstraintDateRule" on page 1654.	String (Enum)	

Table 7.40: PartSourceType (Mfg) fields

Field name	Description	Data type	Key
Constraint MinimumRule	Controls whether the minimum quantity (as defined by **PartSource.MinimumQty**) is used when splitting supplies for constraint allocation (see "Respecting order policy rules" on page 1684) or incremental availability of component materials (see "Respecting order policy rules" on page 1481). Valid values are: • **Ignore**—the effective minimum quantity is not used when splitting supplies for constraints or incremental availability. • **MultiplePeriods**—the effective minimum quantity is used when splitting supplies for constraint or incremental availability (splits must be at least the size of the **PartSource.MinimumQty** value). Note that for constraint allocation, a single order might be allocated constraint from multiple constraint periods (not necessarily contiguous) in order to meet the minimum order quantity. Thus, this value is only compatible with single order **ConstraintDateRule** options (ShipExtend, StartExtend, or DuringLeadTime). Also, this value can be used to enforce minimum order quantities on part sources constrained by fixed constraints. **Note:** Constraint FairShare does not support the combination of PartSourceType.ConstraintMinimumRule with MultiplePeriods. • **Use**—the effective minimum quantity is used when splitting supplies for constraints or incremental availability (splits must be at least the size of the **PartSource.MinimumQty** value). Note that for constraint allocation, the minimum order quantity is enforced within each constraint period (for example, a workday or week). This means there must be sufficient constraint available within a given constraint period to meet the minimum quantity or supply cannot be planned there. Also, for part sources constrained by a fixed constraint, this value is treated the same as Ignore (minimum quantity is not used). **Default value**: Ignore	String (Enum)	

Table 7.40: PartSourceType (Mfg) fields

Field name	Description	Data type	Key
Constraint MultipleRule	Controls whether the lot size (as defined by **PartSource.MultipleQty**) is used when splitting supplies for constraint allocation (see page "Respecting order policy rules" on page 1684) or incremental availability of component materials. This setting is useful for parts that can only be built in defined batch quantities. Valid values are: • **Ignore**—the effective multiple quantity is not used when splitting supplies for constraints or incremental availability. • **MultiplePeriods**—the effective multiple quantity is used; that is, supply splits are multiples of **PartSource.MultipleQty**. Note that for constraint allocation, the order multiple is enforced across multiple constraint periods (for example, workday or week) as necessary. In other words, if an order is allocated constraint from multiple periods, then the total constraint consumed by the order should respect the multiple quantity (but the constraint consumed within just one of those periods might not). This value is only compatible with single order **ConstraintDateRule** options (ShipExtend, StartExtend, or DuringLeadTime) Also, this value can be used to enforce minimum order quantities on part sources constrained by fixed constraints. **Note:** Constraint FairShare does not support the combination of **PartSourceType.ConstraintMultipleRule** with **MultiplePeriods**. • **Use**—the effective multiple quantity is used; that is, supply splits are multiples of **PartSource.MultipleQty**. Note that for constraint allocation, the order multiple is enforced within each constraint period (for example, a workday or week). In other words, a given order can only be allocated constraint from a particular period in the defined multiple quantity. Also, for part sources constrained by a fixed constraint, this value is treated the same as Ignore (multiple quantity is not used). **Default value**: Use	String (Enum)	

Table 7.40: PartSourceType (Mfg) fields

Field name	Description	Data type	Key
CostRule	Specifies how the enterprise system calculates the effective cost of a part. Valid values are: • **UnitCost**—sets the PartSource.EffUnitCost to a fixed value equal to the value imported into the PartSource.UnitCost field or Part.StdUnitCost if UnitCost is 0. If neither of these fields are greater than 0 then the PartSource.EffUnitCost is 0. If PartSource.UnitCost > 0, set PartSource.EffUnitCost = UOMConversion (PartSource.UnitCost). Otherwise, if Part.StdUnitCost > 0, set PartSource.EffUnitCost = Part.StdUnitCost. Otherwise, PartSource.EffUnitCost = 0. • **MaterialLaborOverheadCosts**—calculates the PartSource.EffUnitCost by adding the material, labor, and overhead costs. If PartSource.MaterialCost + PartSource.LaborCost + PartSource.OverheadCost + PartSource.OverheadCost2 > 0 then set PartSource.EffUnitCost to the value of this summation converted to Part UOM (note that if the **PartSourceTimePhasedAttributes** table has an effective record for the part source then its values are used instead of those defined on the **PartSource** record). Otherwise, if Part.StdUnitCost > 0, set PartSource.EffUnitCost = Part.StdUnitCost. Otherwise, PartSource.EffUnitCost = 0. **Default value:** UnitCost **Note:** This setting also impacts the calculation of the **NewPurchaseCost** fields found on many tables in the RapidResponse data model.	String (Enum)	
Description	Additional information about this source type.	String	
DockToStock LeadTimeRule	Specifies whether the **DockToStockLeadTime** value on the **PartSource** record is used in lead time calculations. Valid values are: • **Ignore**—the **DockToStockLeadTime** value is always ignored. • **Use**—the **DockToStockLeadTime** value is used in lead time calculations. If **TransitRule** is set to "Cumulative", then **DockToStockLeadTime** is used in calculating effective lead time and hence the supply start date. Otherwise, if **TransitRule** is "Inclusive", then **DockToStockLeadTime** is only used in determining the calculated dock date **Default value:** Use	String (Enum)	

Table 7.40: PartSourceType (Mfg) fields

Field name	Description	Data type	Key
EffectivityRule	Specifies the effectivity rule that is used by the enterprise system to interpret the dates on PartSource records (which are time phased). Valid values are: • **InclusiveExclusive**—the PartSource record is effective beginning on the "In date" (EffectiveInDate) and ending on the day prior to the "Out date" (EffectiveOutDate). This is the recommended setting. • **Always**—effectivity dates are ignored and PartSource records are treated as effective. • **Exclusive**—the PartSource record is effective beginning on the day after the "In date" (EffectiveInDate) and ending on the day prior to the "Out date" (EffectiveOutDate) • **Inclusive**—the PartSource record is effective beginning on the "In date" (EffectiveInDate) and ending on the "Out date" (EffectiveOutDate). • **Never**—the PartSource record is never used for generating planned orders. However, it is a valid sourcing record for existing scheduled receipts. It is also excluded from the calculation of IsRecursive flags. The PartSource record might be maintained for historical purposes, or as a placeholder to be activated later by setting its EffectivityRule to another value.	String (Enum)	

Table 7.40: PartSourceType (Mfg) fields

Field name	Description	Data type	Key
ExpiryDateRule	Determines the point from which expiring supplies using this part source begin to expire. This is the date to which **PartSource.IntervalsToExpiry** is added to determine the estimated expiry date (used by the Netting analytic) and to which **PartSource.CTPIntervalsToExpiry** is added to determine the actual expiry date (calculated by the Capable-To-Promise analytic) on a given supply. Valid values are: • **DueDate**—The estimated expiry date is calculated by adding **IntervalsToExpiry** to the effective due date, and the actual expiry date is calculated by adding **CTPIntervalsToExpiry** to the available date. This setting should be used when expiration is expected to start from the point the supply is placed into stock. • **DockDate**—The estimated expiry date is calculated by adding **IntervalsToExpiry** to the effective dock date, and the actual expiry date is calculated by adding **CTPIntervalsToExpiry** to the available dock date. This setting should be used when expiration is expected to start from the point when the finished product is received but before it is placed into stock (as represented by the value in the **DockToStockLeadTime** field). For example, there might be an inspection process before a product can be received into stock, but during which it starts to expire. • **StartDate**— The estimated expiry date is calculated by adding **IntervalsToExpiry** to the effective start date, and the actual expiry date is calculated by adding **IntervalsToExpiry** to the available start date. This setting should only be used when all lead time components are meant to be included as part of expiry, and caution should be taken with its usage. If used with variable lead time (**VarLeadTime**), then this setting might result in planned orders that expire sooner than expected and potentially cannot be used. **Default value**: DueDate	String (Enum)	

Table 7.40: PartSourceType (Mfg) fields

Field name	Description	Data type	Key
ExpiryRule	Specifies how the expiry date for supplies from part sources of this type are calculated. The expiry date is then used to determine which demands can potentially be satisfied by the supply. This field is also used by calculations that set the earliest expiry date on dependent demands. By default, the **PartType.ExpiryRule** field sets how expiration is calculated for each part of a given type (from any of its sources), but this can be overridden at the part source level if necessary. Typically, this is done when a part has multiple sources of supply and not all of those sources should have their supply's expiration calculated in the same manner. For example, if supply is provided by a "make" source the expiry date might be calculated based on the part's components, but if it is provided from a "transfer" source then the expiry date might be taken directly from that incoming supply. Note also that the settings in this table are only applicable to parts where **PartType.ExpiryRule** is set to a value other than "Ignore" (if the part is not configured for expiry, then this field is always ignored). Valid values are: • **Dependent**—supplies expire based on characteristics of their components. The supply expiry date is calculated as the earliest expiry date on any component supply used to satisfy its dependent demands. This option is typically used for expiring assembly parts (if used on parts that do not explode to any components, then supply might not actually expire). When an assembly part of this type generates dependent demands on components subject to expiry, then those dependent demands inherit their earliest expiry date directly from the earliest expiry date on the assembly demand. • **DependentLimit**—supplies expire based on either their own characteristics or those of their components. The supply expiry date is calculated as the earliest between its own calculated expiration (**AvailableDate + PartSource.CTPIntervalsToExpiry**) or the **ExpiryDate** found on any component supply used to satisfy its dependent demands. Note that if this option is used on parts that do not explode to any components, then supply might not actually expire. When an assembly part of this type generates dependent demands on components subject to expiry, then those dependent demands inherit their earliest expiry date directly from the earliest expiry date on the assembly demand.	String (Enum)	

Table 7.40: PartSourceType (Mfg) fields

Field name	Description	Data type	Key
	• **DependentStart**—supplies expire based on a mix of their own characteristics and those of their components. The supply **ExpiryDate** is calculated by adding the assembly's **PartSource.CTPIntervalsToExpiry** value to the earliest **ExpiryStartDate** rolled up from any component supply (by default, this will be set to the component's available date but expiry start dates can also be provided on input supplies). Note that this option is typically used for expiring assembly parts that contain limiting components in their structure (parts where **ExpiryType.ProcessingRule** is set to "LimitingComponent"). For more information, see "DependentStart" on page 1619 Note also that when an assembly part of this type generates dependent demands on components subject to expiry, then those dependent demands have their earliest expiry date calculated starting from their own due date and adding the component's **MinimumShelfLife** value (in intervals of the component **ExpiryCalendar**). • **FromPartType**—expiry dates on supplies and earliest expiry dates on dependent demands are calculated based on the part's default setting in the **PartType.ExpiryRule** field. For example, this setting would typically be used on all part's that only have one source of supply. If a part has multiple sources of supply, then this setting can be used on those sources whose expiration should be calculated in the same manner defined by the part's default setting. • **Self**—a supply for a part of this type expires based on its own characteristics. The supply expiry date is calculated by adding the number of **ExpiryCalendar** intervals defined by the **PartSource.CTPIntervalsToExpiry** value to the supply's **AvailableDate**. This option is typically used for expiring assembly parts whose expiry is not determined by their components as well as for bottom-level component parts. When an assembly part of this type generates dependent demands on components subject to expiry, then those dependent demands have their earliest expiry date calculated starting from their own due date and adding the assembly's **MinimumShelfLife** value (in terms of the assembly's **ExpiryCalendar**). • **SelfReset**—supplies for parts of this type expire based on their own characteristics. The supply expiry		

Table 7.40: PartSourceType (Mfg) fields

Field name	Description	Data type	Key
	date is calculated by adding the number of **ExpiryCalendar** intervals defined by the **PartSource.CTPIntervalsToExpiry** value to the supply's **AvailableDate**. This option is intended for use on assembly parts whose components should have the earliest expiry date on their dependent demands calculated to meet their own expiry objectives rather then those of the assembly. It is similar to "Self" except in how it impacts the earliest expiry date on dependent demands. When an assembly part of this type generates dependent demands on components subject to expiry, then those dependent demands have their earliest expiry date calculated starting from their own due date and adding the component's **MinimumShelfLife** value (in intervals of the component **ExpiryCalendar**). **Default value:** FromPartType		
PlannedOrder SupplyStatus	Specifies how to control Order.Line level configuration settings (such as generation of dependent requirements) for planned orders. **Referenced table:** SupplyStatus	Reference	
PlannedOrder SupplyType	Specifies, for planned orders, how to control order level configuration settings (such as rescheduling logic and whether the order is a Make, Buy or Transfer). While PartTypes and PartSourceTypes might have already been named to reflect Make, Buy or Transfer, the SupplyType is the value that defines Make, Buy and Transfer logic and the PlannedOrderSupplyType is the link between these values. **Referenced table:** SupplyType	Reference	
PlannedOrder ToSR SupplyStatus	The supply status used when converting planned orders into scheduled receipts. This value is also used during the part source selection process . **Referenced table:** SupplyStatus	Reference	
PlannedOrder ToSR SupplyType	The supply type to use when converting planned orders into scheduled receipts. This field is also used as part of the criteria for assigning a part source to a scheduled receipt as discussed in "Part sources for scheduled receipts" on page 1389. **Referenced table:** SupplyType	Reference	

Table 7.40: PartSourceType (Mfg) fields

Field name	Description	Data type	Key
PrePlanRule	When supplies are preplanned due to consuming constraint in an earlier period to try and satisfy a demand date, this setting controls the direction in which that constraint is consumed and hence may affect just how early pre-planning is done. Valid values are: • **Normal**— constraint is consumed from earliest date to latest (after having determined the earliest constraint bucket necessary for pre-planning to start. With this setting, preplanned quantities are likely to be seen in earlier constraint buckets, and in some cases preplanning might be seen as starting earlier than strictly required. This corresponds to how pre-planning was always done prior to Version 2016.2, Service Update 16. • **JustInTime**— constraint is consumed from latest constraint bucket to earliest. As necessary, orders are sized to fit available constraint capacity in the latest bucket. This setting is intended to reduce unnecessarily pre-planned quantities. **Default value**: Normal **NOTE**: This field was added in Version 2016.2, Service Update 16.	String (Enum)	
PreShipLead TimeRule	Specifies whether the **PreShipLT** value on the **Source** record is used in lead time calculations. Valid values are: • **Ignore**—the **PreShipLT** value is always ignored. • **Use**—the **PreShipLT** value is used in lead time calculations. If **TransitRule** is set to "Cumulative", then **PreShipLT** is used in calculating effective lead time and hence the supply start date. Otherwise, if **TransitRule** is "Inclusive", then **PreShipLT** is only used in determining the calculated ship date. **Default value:** Use	String (Enum)	
TransitTimeRule	Specifies whether the **TransitTime** value on the **Source** record is used in lead time calculations. Valid values are: • **Ignore**—the **TransitTime** value is always ignored. • **Use**—the **TransitTime** value is used in lead time calculations. If **TransitRule** is set to "Cumulative", then **TransitTime** is used in calculating effective lead time and hence the supply start date. Otherwise, if **TransitRule** is "Inclusive", then **TransitTime** is only used in determining the calculated ship date. **Default value:** Use	String (Enum)	

Table 7.40: PartSourceType (Mfg) fields

Field name	Description	Data type	Key
TransitRule	Specifies how the enterprise system calculates lead time. Lead time values are considered in calculating a "start date" (PlannedOrder.StartDate or ScheduledReceipt.CalcStartDate). Valid values are: • **Cumulative**—lead time, and hence supply start date, is determined as the worst case scenario for producing a part. It is calculated by adding the following fields: PartSource.FixedLeadTime, PartSource.VarLeadTime, Part.LeadTimeAdjust, Source.PreShipLT, Source.TransitTime, and PartSource.DockToStockLeadTime. • **Inclusive**—lead time, and hence supply start date, is considered as the time when a part is ordered until it arrives in stock. Lead time is calculated by adding the following fields: PartSource.FixedLeadTime, PartSource.VarLeadTime, and Part.LeadTimeAdjust. **Note:** For more information about lead-time calculations, see "Lead time calculations" on page 1307. **Default value**: Inclusive	String (Enum)	
UseTimePhasedPartSource LeadTime	Specifies whether any applicable time-phased fixed or dock-to-stock lead time values are applied to the part source. This setting can be used to easily disable time-phased lead time logic without modifying existing input data in the **TimePhasedPartSourceLeadTime** table. Valid values are: • **Y**— time-phased lead time calculations are performed for this part source as long as records exist for it in the **TimePhasedPartSourceLeadTime** table. If a part source does not have any records defined in that table, then stationary lead time values from the **PartSource** table are used instead. • **N**—time-phased lead time calculations are not performed for the part source. This is regardless of whether or not records are defined for it in the **TimePhasedPartSourceLeadTime** table (stationary values from the **PartSource** table are always used). **Default value:** Yes **NOTE**: This field was added in Version 2016.2, Service Update 18.	Boolean	

Table 7.40: PartSourceType (Mfg) fields

Field name	Description	Data type	Key
UseTimePhasedSource LeadTime	Specifies whether any applicable time-phased transit or pre-ship lead time values are applied to the applicable source. This setting can be used to easily disable (or re-enable) time-phased lead time logic without modifying existing input data in the **TimePhasedSourceLeadTime** table. Valid values are: • **Y**—time-phased lead time calculations are performed for this part source as long as records exist for the source in the **TimePhasedSourceLeadTime** table. If a source does not have any records defined in that table, then stationary lead time values from the **Source** table are used instead. • **N**—time-phased lead time calculations are not performed for the part source. This is regardless of whether or not records are defined for the source in the **TimePhasedSourceLeadTime** table (stationary values from the **Source** table are always used). **Default value:** Yes **NOTE**: This field was added in Version 2016.2, Service Update 18.	Boolean	
Value	Identifier for this rule.	String	
PartSources	Set of **PartSource** records that reference this PartSourceType value.	Set	

PartType table

The **PartType** table contains the values that control how a part is processed. By setting up records appropriately, you can emulate the part types (also called source code) from the enterprise data source.

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
Allocation QuantityRule	Specifies whether to include effective quantity in the criteria for sorting supplies and demands before the allotment of supplies to demands. Valid values are: • **Ignore**—Ignores the effective quantity when sorting supplies and demands before the supply-demand allotment. This setting can be used to satisfy demands on a first in, first out basis (if order ids have been assigned sequentially). • **Use**—Includes the effective quantity when sorting supplies and demands before the supply-demand allotment. This setting can be used to try and satisfy as many demands on time as possible (by ensuring smaller demands are satisfied before larger demands when there is insufficient quantity to satisfy all). **Default value**: Use	String (Enum)	
ATPCTPRule	Specifies, for each part type, where excess supply is allocated, and how to calculate for available to promise (ATP). Valid values are: • **Earliest**—demand is satisfied on time; that is, the **IndependentDemand.AvailableDate** will equal the **IndependentDemand.DueDate**. These demands are satisfied with the latest available supply that will satisfy the demand on time. This leaves earlier supplies available as ATP and therefore able to satisfy demands dropped in at the beginning of a scenario. • **Latest**—demand is satisfied with the earliest available supply that will make the **IndependentDemand.AvailableDate** as early as possible. This means ATP is calculated later and based on the remaining supply. **Default value:** Earliest **Note:** This control affects ATP results calculated by the Capable-to-Promise analytic and reported in various calculated fields. It does not affect results in the **AvailableToPromise** table which is based on Netting results.	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
AvailableRule	Specifies how the availability for the part is determined. Valid values are: • **Ignore**—available date is calculated for each supply, but requirements are treated as if the dependent and independent demands had been covered by on hand supplies. Hence, dependent requirements onto these parts are available at Past and independent requirements are available at DataDate. Use this setting for vendor managed parts. • **Normal**—available date for supplies and demands are processed using all the rules for CTP. **Default value:** Normal **Note:** Any expiring parts should typically have this field set to "Normal". For more information, see "Setting a part's expiry rule" on page 1602. **Note:** The setting in this field can be overridden on parts that have their **AvailableRule** reference populated. For more information, see "AvailableRule table" on page 686.	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
CommitLevel	Specifies, for each part type, how order commitments are maintained, and sets how priority is applied to netting (supply planning) and CTP (available date calculations). Valid values are: • **High**—Priority is used in both Netting and CTP. During Netting, priority is propagated from demands to supplies, and demands are processed in priority sequence. During CTP, priority is used when allocating supply to demand. This setting is appropriate for parts that have part sources with constraint and might have components with limited availability. • **MediumExplodePriority**—Priority is used in both CTP and Netting calculations. During Netting, priority is propagated from demands to supplies, however demands are processed in due date sequence instead of priority sequence. During CTP, priority is used when allocating supply to demand. Similar to "High", this setting is appropriate for parts that have part sources with constraint and might have components with limited availability, but is intended for parts set to use lot sizing policies, configured as the primary product in a coproduct byproduct structure, or as the primary component in a BOM level part substitution relationship. • **Medium**—appropriate for parts with only buy sources (with or without constraint) or make sources with no constraint. Priority is used in CTP, but not in netting. This means that priority is not propagated from demands to supplies, nor is priority used when allocating constraint to supplies for this part. However, priority is used when allocating supply to demand. For example, this setting would be used for purchased parts without supplier constraints. • **Low**—appropriate for parts where all part sources have no active constraint and where any make sources have unlimited availability. Priority is not used in either netting or CTP, nor is it used when allocating constraint. A low setting overrides a setting of **Y** on **OrderPriority.MaintainCommitments**. **Default value:** Low	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
ConstraintShare Rule	Specifies whether the part's demands are eligible for the fair-sharing of common constraints with other parts whose sources also require them. The OrderPriority.ConstraintAllocationRule field initially enables or disables the fair-sharing of limited constraint availability for all demands of a given priority level. This setting subsequently allows for constraint-sharing to be either turned off or limited at the part level. For example, it might be used to disable fair-sharing on lower level parts in the product structure who receive dependent requirements with priorities and fair-sharing policies inherited from higher-level assemblies. Valid values are: • **Ignore**—constraint sharing is always disabled for parts of this type, regardless of the setting in the ConstraintAllocationRule field. That is, when satisfying demands of a given priority level, potentially limited constraint is always allocated on a supply-by-supply basis (thus the demands satisfied by those supplies are satisfied on a first-come, first- served basis). • **Use**—constraint sharing is enabled for parts of this type on all demands belonging to priority levels where the ConstraintAllocationRule is set to "FairShare". Thus, when there is limited constraint availability to satisfy all demands on time, it is fairly shared between the sources supplying the different parts (thus, any resulting lateness is also shared between their demands). • **WithinFence**— constraint sharing is enabled for parts of this type on demands having priority levels where the ConstraintAllocationRule is set to "FairShare", and where the demand's due date falls within the constraint sharing window as defined by Part.ConstraintShareFence. Typically, used when the sharing of limited constraint is intended only to satisfy near-term demands, but where first-come, first-served constraint allocations are acceptable later in the planning horizon. **Default value**: Use	String (Enum)	
ControlSet	The control set associated with this PartType record. **Referenced table:** ControlSet	Reference	Yes

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
DaysSupply PrioritySource	For parts subject to days of supply logic (where **UseDaysSupply** = "Y"), this setting controls how the **OrderPriority** field on a **PlannedOrder** record generated in a given period is set. The order priority can be set to the part's default priority or calculated based on the priorities of the demands that the planned order satisfies in Netting. This field applies to all **DaysSupplyRule** options other than "ByPeriodWithPriority" and "ByPeriodWithPriorityEnd". When using either of these settings, a separate planned order is always created for each priority value found on one or more demands being satisfied in a given period. Valid values are: • **Average**—order priority is set to the average of the priorities found on all demands satisfied by the order in Netting calculations. That is, the **OrderPriority**.**PlanningPriority** values found on all demands being satisfied are summed and then divided by the number of demands. The **OrderPriority.Value** associated with the closest **PlanningPriority** value less than or equal to the average is then used. • **Default**—order priority is set to the part's default priority value as found in the **DefaultPriority** field. • **Highest**—order priority is set to the highest priority found on any demand satisfied by the order in Netting calculations. That is, the **OrderPriority.Value** associated with the lowest **OrderPriority**.**PlanningPriority** value referenced from the demands being satisfied is used. • **WeightedAverage**—order priority is set to a weighted average of the priorities found on all demands satisfied by the order in Netting calculations. That is, the **OrderPriority.PlanningPriority** values found on all demands being satisfied are multiplied by their respective demand quantities, summed together, and then divided by the total demand quantity being satisfied. The **OrderPriority.Value** associated with the closest **PlanningPriority** value less than or equal to the average is then used. As opposed to the "Average" option, this setting can help prevent planned order priorities from being inflated due to very small high priority demands. **Default value**: Default In order for demand priorities to be propagated to planned orders as described here, the part's **CommitLevel** setting must be "High". **Note:** For more information, see "Days of supply and planned order priority (alternate configuration)" on page 1371.	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
DaysSupplyRule	For parts where **UseDaysSupply** = 'Y' and the **Part.DaysSupplyPolicy** reference is Null, this field defines the period considered when accumulating demands for planned order generation. Valid values are: • **ByPeriod—**uses the value in **Part.PlanningCalendars.PeriodSupplyInterval** to define the calendar used when accumulating demands (for example, weekly). Demands are accumulated over the number of calendar intervals set by the value in **Part.NumberOfDaysSupply** (starting from the due date of the first unsatisfied demand)**.** A single planned order is then generated on the first **Part.PlanningCalendars.Period SupplyDueIntervalCalendar** interval within the accumulation period. • **ByPeriodEnd**—demands are accumulated in intervals of the **Part.PlanningCalendars. PeriodSupplyInterval** calendar, and over the number of intervals set by the **Part.NumberOfDaysSupply** field (starting from the due date of first unsatisfied demand). A single planned order is then generated on the first **Part.PlanningCalendars.Period SupplyDueIntervalCalendar** interval within the accumulation period. • **ByPeriodEndWithPriority**—uses the value in **Part.PlanningCalendars. PeriodSupplyInterval** to define the calendar used when accumulating demands (for example, weekly), and accumulates demands over the number of calendar intervals set by the value in **Part.NumberOfDaysSupply** (starting from the due date of the first unsatisfied demand). If the **CommitLevel** is set to "High", then this setting also attempts to respect priority by breaking down the accumulated quantity into smaller units grouped by priority. However, if **CommitLevel** is set to "Low", "Medium", or "MediumExplodePriority" priority is ignored and this setting is identical to **ByPeriodEnd**. • **ByPeriodWithPriority**—uses the value in **Part.PlanningCalendars.PeriodSupplyInterval** to define the calendar used when accumulating demands (for example, weekly), and accumulates demands over the number of calendar intervals set by the value in **Part.NumberOfDaysSupply** (starting from the due date of the first unsatisfied demand). If the **CommitLevel** is set to "High", then this setting also attempts to respect priority by breaking down the accumulated quantity into smaller units grouped by priority. These quantities and priorities	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
	are used when generating planned orders whose priorities are subsequently passed down to their dependent demands. However, if **CommitLevel** is set to "Medium", "MediumExplodePriority", or "Low", priority is ignored and this setting is identical to **ByPeriod**. • **FromDemand**—uses the value in **Part.PlanningCalendars.TimeUnits** to define the time unit used when accumulating demands (for example, work days). Demands are accumulated over the number of units set by the value in **Part.NumberOfDaysSupply** (starting from the due date of the first unsatisfied demand). • **FromSupply**—similar to **FromDemand** except that demands accumulate starting from the due date when the supply can be planned (instead of the due date of the unsatisfied demand). In cases where there is a past-due demand for a part subject to **DaysOfSupply**, the supply due date will be later than the demand due date, and hence the days supply horizon will end later. In typical cases where the supply due date and demand due date are the same, this field has the same effect as **FromDemand**. • **Ignore**—Days of supply planning is disabled for parts that use this policy (regardless of the setting in the **UseDaysSupply** field). **Default value**: FromDemand **Note:** For more information, see "Days of Supply calculations" on page 1362.		
DefaultPriority	The default order priority level for parts of this type. This is the priority assigned to new planned orders when **PartType.CommitLevel** is set to either "Medium" or "Low" as discussed in "Priorities on planned orders" on page 1790. . This is also the priority to use for all planned orders resulting from safety stock requirements when using the default **SafetyStockPolicy.DemandTransformationRule** setting of "Ignore". However, when using the "FirstInFirstOut" setting, then priorities on planned orders driven from safety stock requirements are set to the priority of the next subsequent real demand that the supply is seen to satisfy. Additionally, if using time-phased safety stock than priority on safety stock requirements can be explicitly set using the **TimePhasedSafety.OrderPriority** reference. For more information about using priority on safety stock, see "Priority and safety stock holds in CTP" on page 1780. **Referenced table:** OrderPriority **Default value:** OrderPriority with the highest Number.	Reference	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
Dependent Demand Forecast Consumption	For dependent demands having a **Type.ProcessingRule** = 'FromPart', this field determines whether or not the demand for the component consumes forecast. Valid values: • **Y**—any dependent demands for this part that have a **Type.ProcessingRule** of 'FromPart' are processed for forecast consumption (that is, they are treated as if **Type.ProcessingRule** = 'SalesActual'. • **N**—any dependent demands for this part that have a **Type.ProcessingRule** of 'FromPart' are not processed for forecast consumption (that is, they are treated as if **Type.ProcessingRule** = 'Regular'. For more information, see "Dependent forecast consumption on a component by component basis" on page 1442. Default value: **N**	Boolean	
Dependent Demand Usage	Specifies the behavior of the dependent demand generated on each PartType. Valid values are: • **Ignore**—generate but do not use in netting. • **DoNotGenerate**—do not generate any dependent demand on this component • **Net**—Generate dependent demand on this component and use the demand in netting • **BlowThrough**—phantom part processing and dependent demand is passed straight through to components of this part. • **NetIfInventory**—use dependent demand in netting if the part has nettable inventory (**OnHand.Type.ProcessingRule** = 'Nettable'). If not, blow all dependent demand through to components of this part. • **NetIfActive**—Use dependent demand in netting if the part has nettable inventory (**OnHand.Type.ProcessingRule** = 'Nettable'), supply (**ScheduledReceipt.Status.IgnoreSupply** = 'N') or demand (**IndependentDemand.Status.ProcessingRule** = 'Current' and **IndependentDemand.Order.Type.ProcessingRule** not equal to 'Ignore') or dependent demand. If not, blow all dependent demand through to components of this part. **Default value**: Net	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
Dependent SafetyLead TimeRule	Specifies whether orders satisfying dependent demands generated for parts of this type should use **SafetyLeadTime** as defined on the **Part** and/or **PartSource** tables. Note that this setting is only applicable if **UseSafetyTimeLeadTime** is set to either "Y" or "Soft" (safety lead time is always ignored when that option is set to "N") Valid values are: • **FromDemandType**—safety lead time usage on orders satisfying dependent demands for parts of this type is determined by demand type (using the **SafetyLeadTimeRule** setting from the applicable **DemandType** record). • **Ignore**—safety lead time is never applied on orders satisfying dependent demands for parts of this type. • **Use**—safety lead time is always applied on orders satisfying dependent demands for parts of this type. **Default value:** Use	String (Enum)	
Description	A description of this part type. **Default value**: blank string	String	
DTFRule	Specifies how unconsumed forecast before **Part.DTFDate** is processed. Valid values are: • **ForecastDate**—Any unconsumed forecast due before **DTFDate** is always ignored by Netting (supply is not planned to satisfy it).. • **ForecastInterval**—Unconsumed forecast due before the **DTFDate** is generally ignored by Netting, except when the forecast is due within the same **ForecastInterval** as DTFDate. In that case, the unconsumed forecast is treated as being due at DTFDate and Netting will plan supply to satisfy it. **Default value:** ForecastDate	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
ExcessRule	If a part is configured as a global or BOM-level substitute, this setting can be used to specify that only its excess current supply is made available to satisfy other part's demands. Within the excess window defined by **Part.ExcessFence**, existing supply on a part will then be used to satisfy its own demands first before any remainder (excess) is made available for use as a substitute. Valid values are: • **Fence**—If the part is configured as a bom-level substitute component, then its current supply should be used to satisfy any of its own demands first (regardless of order priority). The leftover or "excess" supply is then eligible to satisfy demand from other components. • **GlobalFence**—If the part is configured as a global substitute part, then its current supply should be first used to satisfy any of its own demands (within a given order priority level). The leftover or "excess" supply is then eligible to satisfy demands of the same priority level from other parts for which it has been configured as a substitute. With this setting, planned orders will only be generated to satisfy the part's own demands and not those of parts for which it is a substitute (excess resulting from those planned orders, however, can be made available to other parts). • **GlobalFenceBeforePriority—**If the part is configured as a global substitute part, then its current supply should be first used to satisfy any of its own demands (regardless of their priority level). The leftover or "excess" supply is then eligible to satisfy any demands from other parts for which it has been configured as a substitute. With this setting, planned orders will only be generated to satisfy the part's own demands and not those of parts for which it is a substitute (excess resulting from those planned orders, however, can be made available to other parts). • **Ignore**—Excess is not a consideration in substitution decisions. Input supply on a substitute component is used to satisfy the demands that require it first regardless of whether the demands are its own or those of the primary component in the group. Similarly, input supply on a globally substitutable part is used to satisfy the demands that require it first regardless of whether the demands are its own or those of another part. **Default value:** Ignore **Note:** If a part is configured for both global and BOM-level substitutions, the "GlobalFence" setting is always ignored (treated as "Ignore").	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
ExpiryPastDue Rule	Specifies how the earliest expiry date on past-due demands is calculated. Earliest expiry dates are normally determined starting from the demand due date and then adding the part's minimum shelf life. However, because past-due demands have due dates that are in the past, this results in the calculation of earliest expiry dates that are typically earlier than they should be. Thus, these demands might be allotted supplies which would otherwise be seen as expiring too soon to satisfy them. This field is applicable to all past-due independent demands for expiring parts, as well as past-due dependent demands for expiring parts that reference an **ExpiryRule** setting of either "Self", "SelfReset", or "DependentStart". Valid values are: • **DataDate**— Past-due demands have their earliest expiry dates calculated starting from **Part.PlanningCalendars.DataDate.FirstDate**(typically, this corresponds to today's date)**.** Thus, earliest expiry calculations are performed relative to the current date rather than a point in the past. • **DueDate**—Past due demands have their earliest expiry date calculated starting from their due date. This setting corresponds to how earliest expiry calculations were performed in all versions prior to 2015.3. **Default value:** DueDate	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
ExpiryRule	Specifies how the expiry date for supplies using parts of this type is calculated. The expiry date is then used to determine which demands can potentially be satisfied by the supply. This field is also used by calculations that set the earliest expiry date on dependent demands. Note also that the setting in this field can subsequently be overridden at the part-source level using the **PartSourceType.ExpiryRule** setting. This is intended for cases where a part has multiple sources, and not all of those sources should have their supply's expiration calculated in the same manner. For example, if provided by a "make" source the expiry date might be calculated from the part's components, and if provided by a "transfer" source the expiry date might be inherited from the incoming supply. Valid values are: • **Dependent**—supplies expire based on characteristics of their components. The supply expiry date is calculated as the earliest expiry date on any component supply used to satisfy its dependent demands. This option is typically used for expiring assembly parts (if used on parts that do not explode to any components, then supply might not actually expire). When an assembly part of this type generates dependent demands on components subject to expiry, then those dependent demands inherit their earliest expiry date directly from the earliest expiry date on the assembly demand. • **DependentLimit**—supplies expire based on either their own characteristics or those of their components. The supply expiry date is calculated as the earliest between its own calculated expiration (**AvailableDate + PartSource.CTPIntervalsToExpiry**) or the **ExpiryDate** found on any component supply used to satisfy its dependent demands. Note that if this option is used on parts that do not explode to any components, then supply might not actually expire. When an assembly part of this type generates dependent demands on components subject to expiry, then those dependent demands inherit their earliest expiry date directly from the earliest expiry date on the assembly demand. • **DependentStart**—supplies expire based on a mix of their own characteristics and those of their components. The supply **ExpiryDate** is calculated by adding the assembly's **PartSource.CTPIntervalsToExpiry** value to the earliest **ExpiryStartDate** rolled up from supply of a limiting component (by default, this will be set to the component's available date but expiry start dates can also be provided on input supplies). Note that this option is typically used	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
	for expiring assembly parts that contain limiting components in their structure (parts where **ExpiryType.ProcessingRule** is set to "LimitingComponent"). For more information, see "DependentStart" on page 1619. Note also that when an assembly part of this type generates dependent demands on components subject to expiry, then those dependent demands have their earliest expiry date calculated starting from their own due date and adding the component's **MinimumShelfLife** value (in intervals of the component **ExpiryCalendar**). • **Ignore**— supplies for parts of this type do not expire, and can be used to satisfy demand on any date. The expiry date on supplies is always set to "Future" and the earliest expiry date on demands is always set to "Past". Note also that the **ExpiryRule** setting on the **PartSourceType** table is always ignored for parts using this setting (the part will never expire regardless of the setting at the part-source level). • **Self**—a supply for parts of this type expires based on its own characteristics. The supply expiry date is calculated by adding the number of **ExpiryCalendar** intervals defined by the **PartSource.CTPIntervalsToExpiry** value to the supply's **AvailableDate**. This option is typically used for expiring assembly parts whose expiry is not determined by their components as well as for bottom-level component parts. When an assembly part of this type generates dependent demands on components subject to expiry, then those dependent demands have their earliest expiry date calculated starting from their own due date and adding the assembly's **MinimumShelfLife** value (in terms of the assembly's **ExpiryCalendar**). • **SelfReset**—supplies for parts of this type expire based on their own characteristics. The supply expiry date is calculated by adding the number of **ExpiryCalendar** intervals defined by the **PartSource.CTPIntervalsToExpiry** value to the supply's **AvailableDate**. This option is intended for use on assembly parts whose components should have the earliest expiry date on their dependent demands calculated to meet their own expiry objectives rather then those of the assembly. It is similar to "Self" except in how it impacts the earliest expiry date on dependent demands. When an assembly part of this type generates dependent demands on components subject to expiry, then those dependent demands have their earliest expiry date calculated starting from their own due date and adding the component's **MinimumShelfLife** value (in intervals of the component		

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
	ExpiryCalendar). **Default value:** Ignore Any expiring parts should typically have their applicable **AvailableRule.ProcessingRule** or **Type. AvailableRule** value set to "Normal". For more information, see "Setting a part's expiry rule" on page 1602.		
FeatureBOM Rule	Used to enable or disable feature BOM logic for configurable end-item assembly parts of this type. When feature BOM logic is enabled, dependent demands are placed on particular assembly components by matching features specified on the demand (**IndependentDemand.FeatureList**) against feature rules that are specified on each BOM record (**BillOfMaterial.FeatureRule**). When feature BOM logic is disabled, dependent demands are placed on all of the assembly's components and any specified features or feature rules are ignored. Valid values are: • **HighVolume**—feature BOM logic is enabled. This setting is intended for configurable end-item assemblies that are expected to have extremely large volumes of orders per day which might impact system performance when performing certain full-level pegging calculations. As such, this setting limits or aggregates certain results returned by the full-level pegging analytic. Specifically, for records pertaining to component supplies in the **WhereConsumed** table, the driving demand is not reported and instead the associated **CTPPlannedOrder** record is reported as the driver. Further, in the **WhereConsumedForSupply** table only one record per planned order for a top-level part is reported, and multiple allotments from the same planned order are not reported. • **Ignore**—feature BOM logic is disabled and normal BOM explosion logic applies. • **Normal**—feature BOM logic is enabled. This setting is intended for configurable end-item assemblies that are not expected to have extremely large volumes of orders per day. With this setting, all full-level pegging calculations are performed and reported as normal. **Default value:** Ignore **Note:** When a part is enabled to be a configurable end-item, its demands can only be satisfied by planned orders (and not any input supplies).	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
Forecast Consumption Calendar	Specifies the calendar whose intervals are used in setting the forecast consumption window for demands on parts of this type. The forecast consumption window defines the date range over which a given actual demand can consume forecast. This window is, by default, set based on the demand's due date with a number of **Part.BeforeForecastInterval** calendar intervals added before the demand's due date and a number of **Part.AfterForecastInterval** calendar intervals added after the demand's due date. These two fields are assumed to be expressed in terms of the calendar chosen here. Valid values are: • **ForecastCalendar**—the forecast consumption window is defined in terms of the part's **PlanningCalendars.ForecastCalendar** value. For example, this might be a monthly calendar. • **SecondCalendar**—the forecast consumption window is defined in terms of the part's **PlanningCalendars.SecondCalendar** value. For example, this might be a workday calendar. **Default value:** ForecastCalendar **Note:** Based on configuration settings in the **ForecastConsumptionDateRule** field on both the **PartType** and **DemandStatus** tables, a given demand's forecast consumption window might be based on the **DataDate** or its **RequestDate** instead of **DueDate**.	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
Forecast Consumption DateRule	Specifies the date from which the forecast consumption window for both independent and dependent demands is derived for parts of this type. Note that the impact of this setting is only seen on demands that are past due. Valid values are: • **DataDate**—demands for parts of this type have their forecast consumption window based on the later of **Part.PlanningCalendars.DataDate** or their **DueDate**. With this setting, past due demands will consume forecast relative to the current date rather than their due date (where there will typically be more forecast available to be consumed). • **DueDate**—demands for parts of this type always have their forecast consumption window based on their **DueDate**. With this setting, past due demands will consume forecast relative to the date past when they were originally due (where there will typically be less forecast to be consumed). **Default value**: DueDate **Note:** This field can be overridden on specific independent demands using the **DemandStatus** table's **ForecastConsumptionDateRule** setting which also includes an option to derive the forecast consumption window from the demand's **RequestDate**.	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
Forecast Consumption Order	Specifies the direction in which a customer order consumes forecast within its forecast interval. • **AlternatingBackward**—Forecast records are consumed starting from the customer order date, moving backward to the beginning of the previous calendar interval defined by Part.PlanningCalendars.SecondCalendar, and then alternating forward and backward in SecondCalendar intervals. • **AlternatingForward**—Forecast records are consumed starting from the customer order date, moving forward to the end of the next calendar interval defined by Part.PlanningCalendars.SecondCalendar, and then alternating backward and forward in SecondCalendar intervals. • **Backward**—Forecast records are consumed starting from the end of the forecast interval, and moving backwards to the start of the forecast interval. • **Forward**—Forecast records are consumed starting from the start of the forecast interval, and moving forwards to the end of the forecast interval. • **Normal**—Forecast records are consumed starting from the record on or before the customer order date, and moving backwards to the start of the forecast interval. After the start of the forecast interval is reached, consumption continues from the first record after the customer order date, and moving forwards to the end of the forecast interval. • **NormalNested**—Forecast records are consumed from the record on or before the customer order date, and moving backwards to the start of the forecast interval that contains the customer order date. After the start of the interval is reached, forecast is consumed from the customer order date to the end of the customer order's interval. Consumption then continues backwards from the start of the customer order's forecast interval to the start of the forecast interval, and then forward from the end of the customer order's interval to the end of the forecast interval. **Default value**: Normal **Note:** For all settings in this field other than AlternatingBackward and AlternatingForward, the forecast consumption window can be defined in terms of either the ForecastCalendar or the Second Calendar (based on the setting in **PartType.ForecastConsumptionCalendar**). For more information about forecast consumption, see "Forecast consumption" on page 1431.	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
Independent SafetyLead TimeRule	Specifies whether orders satisfying consensus forecast or independent demands for parts of this type should use **SafetyLeadTime** as defined on the **Part** and/or **PartSource** tables. Note that this setting is only applicable when **UseSafetyTimeLeadTime** is set to either "Y" or "Soft" (safety lead time is always ignored if that option is set to "N") Valid values are: • **FromDemandType**—safety lead time usage on orders satisfying consensus forecast or independent demands for parts of this type is determined by demand type. This is determined form the **DemandType.SafetyLeadTimeRule** field setting referenced by the applicable **IndependentDemand** or **PartCustomer** record). If the applicable **PartCustomer**record has a Null reference to **DemandType**, then a value of "Use" is assumed. • **Ignore**—safety lead time is never applied on orders satisfying consensus forecast or independent demands for parts of this type. • **Use**—safety lead time is applied on orders satisfying consensus forecast or independent demands for parts of this type. **Default value:** Use	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
OnTimeAllocation Rule	Following the normal allotment of supply to demand in CTP, this setting specifies whether any late supplies for the part can potentially be reallocated to improve the on-time quantity of demands. This process attempts to maximize the total on-time quantity across late demands for the part at the risk of making the available date on late demands worse than they otherwise would be. Valid values are: • **ImproveWithTolerance**—After the normal allotment of supply to demand, additional logic attempts to improve the total on-time quantity on late demands even if doing so makes the calculated available date on some or all of those late demands worse. When not all demands can be satisfied on time, any supplies that are late to their demand (or later than a tolerance defined in **Part.UnsatisfiedDemandTolerance**) are subject to additional on-time reallocation logic. Thus, any demand that is available late (or later than the number of forecast intervals specified in the **UnsatisfiedDemandTolerance** field) can potentially have its on-time quantity improved and/or its final available date made worse. • **Normal**—Normal allotments of supply to demand as made by capable-to-promise logic are used. If not all demands can be satisfied on time, the normal behavior of allocating limited supply to demands based on priority, earliest due date, and so on is used. **Default value**: Normal **NOTE**: This field was added in Version 2016.2, Service Update 27. For more information about its usage, see "Improve on-time quantity by reallocating late supply" on page 1471.	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
OrderPointDate Rule	Indicates the date on which scheduled supply (scheduled receipts, inventory transfers, and supply allocations) for order point parts should be included when calculating whether the threshold for creating new planned orders has been crossed. Valid values are: • **Due**—Scheduled supply is considered as of its ReschedDate (calculated due date). As a result, supply that is already started, but not yet due, is ignored when determining if the order point threshold has been reached. Planned orders might therefore be created to cover this timing gap. . • **Start**— Scheduled supply is considered as of its CalcStartDate (calculated start date). As a result, the order point threshold will not be crossed if a sufficient quantity is available in a started, but not yet due, scheduled supply. This is the recommended value. **Default value**: Due **Note:** This field is only used by parts that have a Null reference in **Part.SafetyStockPolicy** (otherwise, if that reference is populated then the corresponding field on the **SafetyStockPolicy** record is used instead). Use of this field provides backward compatibility with versions prior to 2014.4.	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
OrderPoint Increase	Indicates if a temporary increase in a part's order point threshold should be considered to guard against near-term spikes in demand that might push inventory below zero before more supply can be planned. This setting is only applicable to order point parts (that is, parts where **SafetyStockRule** is set to either "OrderPointAverage", "OrderPointOver", or "OrderPointUnder"). Additionally, this setting relies on the part's **PlanningCalendars.OrderPointIncrease** setting which specifies a calendar whose intervals are used, starting from the RunDate, to look for demand within the part's lead time. Valid values are: • **Calculate**— an increase in the order point is considered for each **PlanningCalendars.OrderPointIncrease** interval where there is demand within lead time. If the demand within lead time (plus any additional demand within the OrderPointIncrease interval) exceeds the effective order point, then the amount it exceeds it by is temporarily added to the order point. This increase is effective until the next OrderPointIncrease interval. • **Ignore**—order point threshold is never inflated to cover spikes in demand that will consume supply before it can be replenished. • **Sum**— an increase in the order point is considered for each **PlanningCalendars.OrderPointIncrease** interval where there is either demand within lead time or a value is provided in the **TimePhasedSafety** table. If the demand within lead time (plus any additional demand within the OrderPointIncrease interval) exceeds the effective order point, then the amount it exceeds it by is temporarily added to the order point. As well, if an effective record is found in the **TimePhased Safety** table, then its quantity is also added to the effective order point (if multiple **TimePhasedSafety** entries are found in the interval then the one with the largest **Quantity** is used). The total increase is effective until the next OrderPointIncrease interval. Note that if **SafetyStockQuantity** is "TimePhasedQuantity" or "TimePhasedQuantityToLatest", then this option and **Calculate** are the same. • **SumOffset**—identical to Sum, except that increases are never performed in the first interval (containing the SafetyStockDate). **Note:** This field is only used by parts having a Null reference in **Part.SafetyStockPolicy**, and gives backward compatibility with versions prior to 2014.4 (prior to **SafetyStockPolicy** table).	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
ProcessingRule	Specifies, for each PartType, a processing rule that describes the logic used for netting calculations. Valid values are: • **Ignore**—do not process this part. All supply and demand records for this part are ignored by netting and do not display in the Activity Table. Because all supply and demand are ignored, no planned orders or available to promise records are generated. This value is often used for reference or vendor managed parts. • **MRP**—Process the part as a standard MRP part. Forecast records (Independent demands with an **Order.Type.ProcessingRule** = 'SalesForecast') are ignored by netting. Available to promise records are not generated. Planned orders are created. • **MPS**—Forecast records (independent demands with a **DemandType.ProcessingRule** = 'SalesForecast') are consumed by sales orders (independent demands with a **DemandType.ProcessingRule** = 'SalesActual'). Available to promise records are generated. Forecast records (independent demands with a **DemandType.ProcessingRule** = 'ProductionForecast') are NOT consumed by sales orders but are valid demand for MPS Parts. • **MPSConfig**—used to explode forecast on a parent part and drive demand to its component parts. This configuration is used for forecasting by product family. The part representing the product family has a **PartType** of MPSConfig (planning BOMs, which are created to define the relationship between the forecasted part and its components, and have MPSConfigDemandSource = 'Y'). Actual demand for component parts consumes forecast at the parent part. Unconsumed forecast results in planned orders and constraints are ignored. No other types of supply or demand qualify for netting on MPSConfig parts. **Default value:** MRP **Note:** If a part does not have at least one active part source, then it is not processed by Netting logic regardless of the setting in this field (always treated as if it were set to "Ignore").	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
SafetyLeadTimeCalendarRule	Specifies the calendar used for safety lead time values provided on the **Part**, **PartSource**, and/or **SafetyLeadTimeProfileDetail** tables. Safety lead time is applied as a buffer against demand dates when determining planned order due dates for the part. Valid values are: • **Everyday**—Safety lead time is expressed in terms of the standard Everyday (Gregorian) calendar. This setting allows non-working days to count towards safety lead time. • **TimeUnits**— Safety lead time is expressed in terms of the part's **PlanningCalendars.TimeUnits** calendar (typically, this is a Workday calendar). This setting corresponds to how safety lead time was always applied prior to Service Update 1902. **Default value**: TimeUnits **Note:** This field was added in Service Update 1902. **Note:** Any demands that do not fall on the part's **PlanningCalendars.TimeUnits** calendar are first rounded back to the nearest **TimeUnits** interval before applying safety lead time (regardless of the setting in this field).		

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
SafetyStockDate Rule	Specifies, for each part type, the date on which to plan for safety stock. Valid values are: • **FirstDemand**—maintain safety stock level as of the date of the earliest demand record. The **PlannedOrder.DueDate** will be on the date of the first demand - (**Part.SafetyLeadTime + PartSource.SafetyLeadTime)**. • **FirstDemandOrLeadTime**—if the part has demands, then a planned order is generated to cover safety stock at the date of the first demand. If the part has no demands, then a planned order is generated to cover safety stock at either **RunDate + LeadTime** (if **OrderPolicy.OrderGenerationRule** is 'AnyTime' or 'AfterRunDate'), OR at the later of **RunDate + LeadTime** or **PTFDate** (if **OrderPolicy.OrderGenerationRule** is 'AfterPTF'). • **FirstDemandOrRunDate**—if the part has demands, then a planned order is generated to cover safety stock at the date of the first demand. If the part has no demands, then a planned order is generated to cover safety stock at either **RunDate** (if **OrderPolicy.OrderGenerationRule** is 'AnyTime' or 'AfterRunDate'), OR at **PTFDate** if **OrderPolicy.OrderGenerationRule** is 'AfterPTF'). • **FirstDemandOrPast**—if the part has demands, then generate a planned order to maintain safety stock at the date of the first demand. If the part has no demands, then a planned order is generated to cover safety stock at either **Past** if **OrderPolicy.GenerationRule** is 'AnyTime', OR at **RunDate** if **OrderPolicy.GenerationRule** is 'AfterRunDate', or at **PTFDate** if **OrderPolicy.OrderGenerationRule** is 'AfterPTF'. • **LeadTime**—maintain safety stock level after RunDate (**Part.PlanningCalendars.RunDate.Value**) + **Part.FixedLeadTime** + **Part.LeadTimeAdjust** + **PartSource.Source.TransitTime** + (**Part.VariableLeadTime** * **Part.SafetyStockQty**). This calculation would result in a due date for the planned order to satisfy safety stock. If either or both of **Part.SafetyLeadTime** or **PartSource.SafetyLeadTime** is greater than 0 then this is added to the above calculation in creating the DemandDate on the PlannedOrder. The objective is to have the **PlannedOrder.StartDate** be achievable. However, lot sizing or other demands may make the start date earlier in the presence of **PartSource.VarLeadTime**. OnHand values may make the actual **PlannedOrder.Quantity** less and thus the **PlannedOrder.StartDate** later. • **LeadTimeReportUnplanned**—similar to the “LeadTime” option in that safety stock is only maintained/planned	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
	after RunDate plus applicable lead times. However, with this setting safety stock levels are still calculated, for reporting purposes only, within lead time. These unplanned safety stock levels are reported in the Activity table with a Type value of "UnplannedSafety". • **Past**—maintain safety level even if it means placing a past due order. The **PlannedOrder.DueDate** may be Past. • **RunDate**—maintain safety stock level only after **Part.PlanningCalendars.RunDate.Value**. The due date of a planned supply would be equal to the run date. A planned order will have a DemandDate associated to it if this rule is used, and the DemandDate would be RunDate + SafetyLeadTime. Ordering policies or planning time fence may override any of these values. **Default value:** LeadTime **Note:** This field is only used by parts that have a Null reference in **Part.SafetyStockPolicy** (otherwise, if that reference is populated then the corresponding field on the **SafetyStockPolicy** record is used instead). Use of this field provides backward compatibility with versions prior to 2014.4. **Note:** When using the "LeadTime" or "LeadTimeReportUnplanned' settings, the lead time from the part's primary part source is used in determining the date from when safety stock can be planned. For example, if a secondary part source has shorter lead time and is used to satisfy a safety stock demand, it still cannot plan it any earlier than **RunDate** plus lead time from the primary part source. **Note:** This field was modified in Version 2016.2, Service Update 8.		

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
SafetyStock QuantityRule	Specifies how safety stock level is determined. Valid values are: • **FixedQuantity**—safety stock level calculated as a fixed quantity using the value in **Part.SafetyStockQty**. • **FractionOfDemand**—safety stock levels calculated the same as PercentOfDemand, except that the value is interpreted as a fraction (for example, 0.1 means 10%). • **PercentOfDemand**—safety stock levels calculated using a percentage (for example, 10 means 10%) of MRP total demand per defined interval. Demand intervals are calculated (beginning from the maximum of the **Part.PlanningCalendar.RunDate** or safety stock date) using the **Part.SafetyStockPolicy.PercentSafety Interval** value. The number of intervals is calculated using the **Part.PercentSafetyIntervalCount** value. All demands during this interval are summed and the **Part.PercentSafetyPercent** is applied against the total demand quantity which results in a DynamicSafetyStock quantity for that interval. • **RangeOfCoverage**—safety stock levels are calculated to satisfy a specified number of days of a part's average daily requirements, and can be configured for three distinct date zones. All parameters used to calculate these safety stock levels are configured through range of coverage profiles in the **RangeOfCoverage** table. If this option is selected for a part, the part's range of coverage profile is taken from the value in **SafetyStockPolicy.RangeOfCoverage**. For more information, see "RangeOfCoverage table" on page 855. • **RangeOfCoverageLeadTime**—safety stock levels are calculated to satisfy the part's average daily requirement over its lead time plus an optional buffer quantity. Most parameters used to calculate these safety stock levels are configured through range of coverage profiles in the RangeOfCoverage table. However, with this setting only the first zone is active and the average daily requirement is multiplied by lead time rather than the FirstZoneTarget value. • **TimePhasedQuantity**—safety stock levels change over time. The TimePhasedSafety table must be populated with the following fields: Part, Site, Date (earliest date this safety stock quantity is applicable), and Quantity. For example, safety of 5 is effective beginning 01-01-05 and a quantity of 10 is effective beginning 06-01-05. This means that a safety stock of 5 is no longer effective as of 05-31-05. For more information, see "TimePhasedSafety table" on page 655. This setting is identical to TimePhasedQuantityToLatest except in cases where the	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
	part's safety stock level decreases after the last demand. • **TimePhasedQuantityToLatest**—This setting is identical to TimePhasedQuantity except in cases where the safety stock level decreases after the last demand for the part. If the safety stock level decreases after the last demand for the part, then the quantity of the last planned order will be reduced to ensure the resulting inventory level meets the latest value defined in the TimePhasedSafety table. If using lot sizing, the OrderPolicy.LotSizeLastOrder field should be set to "N" to ensure this behavior. Otherwise, if OrderPolicy.LotSizeLastOrder is set to "Y", then last planned order will only get as close as it can to the latest defined safety stock level while still respecting all lot-sizing rules. • **TimePhasedRangeOfCoverage**—safety stock levels are calculated to satisfy a specified number of days of a part's average daily demand, and are configurable for any number of zones. When using this setting, records in the TimePhasedSafety table are used to define the start of each range of coverage zone as well as the number of days of the part's average daily requirement that safety stock should cover in each of those zones. Additionally, parameters from the RangeOfCoverage table are used to specify how demands are collected for use in calculating the average daily requirement, as well to set the calendar whose intervals can be used to generate new safety stock levels. **Default value:** FixedQuantity **Note:** This field is only used by parts that have a Null reference in **Part.SafetyStockPolicy** (otherwise, if that reference is populated then the corresponding field on the **SafetyStockPolicy** record is used instead).		

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
SafetyStockRule	Specifies, for each part type, the rule used to control the maintenance of safety stock. For example, under what conditions will orders to replenish safety stock be generated? Valid values are: • **Always**—always maintain safety stock level as determined by the **SafetyStockQuantityRule** setting. If an order is required to bring inventory to the **Part.SafetyStockQty,** then generate a planned order or expedite an existing order as early as allowed based on order rescheduling rules (**Type.ProcessingRule /Status.RescheduleRule)**, Order generation rules (**PartSource.OrderPolicy.OrderGenerationRule**) and the **Part.SafetyStockDate** rule. • **IfActivity**—if there are non-ignored ScheduledReceipts (**Status.IgnoreSupply** does not equal 'Y' or the Quantity does not equal 0) or non-ignored IndependentDemand (**Order.Type.ProcessingRule** does not equal 'Ignore', **Status.ProcessingRule** does not equal 'Ignore', or Quantity is not equal to 0) or dependent demands. • **IfDemand**—orders for bringing inventory to safety level will be generated only if there is a non-ignored demand record for the part (**Order.Type.ProcessingRule** does not equal 'Ignore', and **Status.ProcessingRule** does not equal 'Ignore' or quantity is not equal to 0). This includes dependent and independent demand. • **Ignore**—do not maintain safety stock. Ignore the effective safety stock level. • **OrderPointAverage**—orders are generated when inventory levels fall below the order point threshold as determined by the setting in the **SafetyStockQuantityRule** field. The order quantity is determined by the value in **Part.AverageQty** (or **Part.SafetyStockQty** if **Part.AverageQty** is less than or equal to 0), and orders of this size are generated until inventory levels meet or exceed the calculated order point threshold. The start date of the generated planned orders matches the DueDate of the demand they are satisfying. • **OrderPointOver**—orders are generated when inventory levels fall below the order point threshold as determined by the setting in the SafetyStockQuantityRule field. Order quantities are set to the largest number that will bring inventory levels closest to the maximum of either the order point threshold or Part.AverageQty without exceeding it. If using this setting, it is recommended to have SafetyStockQuantityRule set to "FixedQuantity", and ensure Part.AverageQty is set to a value greater than Part.SafetyStockQty. RapidResponse will then plan orders using these two fields as an upper and lower bound,	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
	respectively. • **OrderPointUnder**—orders are generated when inventory levels fall below the order point threshold as determined by the setting in the **SafetyStockQuantityRule** field. Order quantities are set to the smallest number that will bring inventory levels equal to or greater than the maximum of either the order point threshold or **Part.AverageQty**. This setting is intended to keep inventory levels above the order point threshold. The start date of the generated planned orders will match the DueDate of the demand they are satisfying. • **Soft**—safety stock is an available buffer. ReschedDate and RecommendedDate are left as DueDate if existing supplies retain inventory >=0 rather than >= SafetyStock. **Default:** Always **Note:** This field is only used by parts that have a Null reference in **Part.SafetyStockPolicy** (otherwise, if that reference is populated then the corresponding field on the **SafetyStockPolicy** record is used instead). Use of this field provides backward compatibility with versions prior to 2014.4.		
SalesActual Consumption Order	Specifies the order in which sales actuals are used to consume a part's forecast. Valid values are: • **ByDueDate**—Actual demands are used for consumption in due date order (earliest due actuals attempt to consume forecast first). • **ByPriority**— Actuals demands are used for consumption in priority order (higher priority actuals attempt to consume forecast first). If there are multiple sales actuals with the same priority, then the earliest due of those actuals consume forecast first. If **PartType.CommitLevel** is set to "Low", this setting is identical to "ByDueDate" (priority is not considered). When multiple sales actuals with the same due date are eligible to consume forecast based on the settings described above, then the independent demand with the lower **Order.Id** consumes first (or the demand with the smaller **Quantity** if the Ids are the same). **Default value**: ByDueDate **Note:** This field was added in Version 2016.2, Service Update 3.	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
Substitution Preference	Defines the sequence in which global part substitution logic uses different types of supply when trying to satisfy demand for the primary part configured in a substitute part relationship (this setting is only applicable to those primary parts). Note that within the different options described below, a preference between supply of a primary part and supply of its substitutes is determined based on comparing the value in the primary part's **Part.PrimarySubstitutionSequence** field, and the **AlternatePart.Sequence** field value associated with each of its substitutes. Input supply from part's associated with lower sequence values are generally used first (and only substitutes having a higher sequence value than the primary are eligible to have new planned orders created to satisfy demand from the primary part). Valid values are: • **OnHand**—preference is to satisfy primary part demand with existing on-hand inventory. That is, RapidResponse first looks for on hand inventory of the primary and substitute parts. If the demand remains unsatisfied, then scheduled receipts for primary and substitute parts are considered. If the demand still cannot be satisfied, then RapidResponse tries to create an on-time planned order for the primary part, and if this is not possible then it tries to create an on-time planned order on an eligible substitute. Finally, if the demand still cannot be satisfied, then the least late planned order is created on the primary or any of its eligible substitutes. • **Primary**—preference is to satisfy primary part demand with part's having lower **PrimarySubstitutionSequence** (primary) or **Sequence** (substitute parts) values. That is, RapidResponse first looks for on hand inventory of the part having the lower sequence value, followed by scheduled receipts of the part having the lowest sequence value, and then tries to create on-time planned orders for the part with the lowest sequence value (if eligible). If the demand still cannot be satisfied, then RapidResponse will look for supplies of the part having the next lowest sequence value. If, after all parts have been evaluated in sequence order, the demand still remains unsatisfied, then RapidResponse creates the earliest possible planned order for either the primary part or one of its eligible substitutes. • **ScheduledSupply**—preference is to satisfy primary part demand with existing on-hand inventory or scheduled supply. RapidResponse first looks for on hand inventory and then scheduled receipts of the primary part and/or its substitutes. Otherwise, if the demand cannot be satisfied by input supplies, then RapidResponse tries to create an on-time planned order for the primary part, and if this is	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
	not possible then it tries to create an on-time planned order on an eligible substitute. Finally, if the demand still cannot be satisfied, then the least late planned order is created on the primary or any of its eligible substitutes. For more information on substitution sequences and how they are used with the different settings in this field, see "Define when part substitutes are used" on page 1553. **Default**: ScheduledSupply		
Supply Allocation Rule	Specifies how supplies are allocated to demands during capable-to-promise calculations. Supplies are allocated to demands to try to satisfy demand dates. However, where supplies are unavoidably late, the late supplies are allocated to lower priority demands and higher priority demands are kept on time (or as close to on time as possible). Valid values are: • **ByAvailable**—Supplies are allocated by their available date (that is, the date that capable-to-promise calculations determine the supply should be available based on materials and constraint). In cases of expiring supply, when multiple supplies are available to satisfy a demand on time, those supplies are then allocated based on expiry date (earliest expiring supplies are used first). • **ByMRPPlan**—Supplies are always allocated by their demand date (either ScheduledReceipt.DemandDate or PlannedOrder.DemandDate). Demand date refers to the date of the first demand netting calculations determine should be satisfied by the supply. This setting is useful when an allotment results consistent with Netting calculations and certain enterprise systems is desired. However, this setting is generally not recommended as it gives allocation results that do not consider prioritized or constrained demands. **Default:** ByAvailable	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
SupplyShareRule	Specifies whether the part's demands are eligible for the fair or equal sharing of limited supplies. The **OrderPriority.AllocationRule** field is used to initially enable either the fair-sharing or equal-sharing of supply for all demands at a given priority level. This setting then allows for that supply sharing logic to be either turned off at the part level, or kept within a defined time horizon. For example, parts at one level in the product structure might need limited supplies to be shared amongst their High priority demands, while parts at another level in the product structure might not require supply sharing logic for their High priority demands. Valid values are: • **Ignore**—supply sharing is always disabled for parts of this type, regardless of the setting in the AllocationRule field. That is, when satisfying part demands of a given priority level, supplies are always allocated to those demands on a first-come, first-served basis. • **Use**—supply sharing is enabled for parts of this type on all demands belonging to priority levels where the AllocationRule is set to either "FairShare" or "EqualShare". Thus, when there is insufficient supply available to satisfy all prioritized on time, the supply is fairly or equally shared between all demand at a given priority level (thus, any resulting lateness is also shared between those demands). • **WithinFence**— supply sharing is enabled for parts of this type on demands having priority levels where the AllocationRule is set to either "FairShare" or "EqualShare", and where the due date falls within the supply sharing window as set by Part.SupplyShareFence. Typically, used when the sharing of limited supplies is intended only to satisfy near-term demands for the part, but where first-come, first-served supply allocations are acceptable later in the planning horizon. **Default value**: Use	String (Enum)	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
UseDaysSupply	Specifies whether a days of supply policy is used to accumulate demands and group planned orders based on settings in the **Part**, **PartType**, and **PlanningCalendars** table. Note that if there is a non-Null reference in **Part.SafetyStockPolicy**, then the referenced policy enables or disables days of supply logic and this setting is ignored. Valid values are: • **Y**—use Part.NumberOfDaysSupply to group planned orders according to the setting in DaysSupplyRule. Planned orders are grouped for the lesser of 'n' time units/periods or until a non-reschedulable supply (ScheduledReceipt.SupplyType.ProcessingRule = 'NonReschedulable') is seen. Planned order quantities will not exceed the PartSource.MaximumQty. • **N**—Part.NumberOfDaysSupply value is ignored. **Caution:** Avoid using UseDaysSupply with parts with components or constraint. UseDaysSupply can cause order commitments to be violated by new demands (Increased supply quantity may result in a supply being late, thereby making all demands for that supply late). **Recommendation:** Use part source ship calendars, rather than days supply, to align periodic deliveries. **Default value**: N **Note:** In most circumstances, UseDaysSupply = 'Y' overrides CommitLevel. However, if a rule that respects priority is applied (such as **ByPeriodEndWithPriority** and **ByPeriodWithPriority**), CommitLevel is used and priority is maintained.	Boolean	
UseLeadTime Adjust	Specifies, for each part type, whether a lead-time adjustment is applied on a part basis (aside from standard fixed, variable, and safety lead times). Valid values are: • **Y**—use **Part.LeadTimeAdjust** when calculating lead time. • **N**—do not use **Part.LeadTimeAdjust** when calculating lead time. **Default value:** Y	Boolean	
UseLTForFlatBill	Specifies whether a lead-time offset is included when calculating the FirstDate and LastDate fields in the FlatBillDown table. Valid values are: • **Y**—lead time is included. • **N**—lead time is ignored. **Default value**: Y	Boolean	

Table 7.41: PartType (Mfg) fields

Field name	Description	Data type	Key
UseNegativeOnHand	Specifies, for each part type, whether Negative Onhand quantities are considered in netting. Valid values are: • **Y**—negative total nettable on hand is treated as a demand at time Past. • **N**—any negative on hand is ignored. **Default value**: N	Boolean	
UseSafetyLeadTime	Determines whether **SafetyLeadTime** values as specified on the **PartSource, Part**, and/or **SafetyLeadTimeProfileDetail** tables are used for parts of this type. For example, when setting a planned order due date, safety lead time can be used to offset the demand due date to account for fluctuations in supply and demand (the supply is planned earlier than actually required by the demand). Valid values are: • **Y**—safety lead time is always used for parts of this type. • **N**—safety lead time is never used for parts of this type. • **Soft**—safety lead time is used for parts of this type, however reschedule recommendations are suppressed on scheduled receipts whose DueDate satisfies the demand due date. **Note: IndependentSafetyLeadTimeRule** and **DependentSafetyLeadTimeRule** settings provide further control over how safety lead time is applied when planning orders to satisfy specific types of demand. **Note:** If safety lead time should be applied to customer request dates, then the use of settings on the **OrderPriority.TwoDatePlanningRule** field, such as "UseWithHardSafetyLeadTime" or "UseWithSoftSafetyLeadTime", should be considered. **Default value:** N	String (Enum)	
Value	The string value for the part type. This value appears in the part record. **Default value**: blank string	String	Yes
Parts	Set of **Part** records that reference this PartType value.	Set	
PoolMaps	Set of **PoolMap** records that reference this PartType value.	Set	

PlanningCalendars table

Part calendars give the working schedule information for calculating dates. Multiple **PlanningCalendars** records can be used to allow different parts to have different operating schedules. Purchase parts may operate on schedules defined by the vendor.

Table 7.42: PlanningCalendars (Mfg) fields

Field name	Description	Data type	Key
Allocation Calendar	The calendar giving the dates for intervals to perform fair-share and equal-share allocation. All demands with the same **OrderPriority** value in the interval are used in the allocation calculation. This calendar also defines the intervals used for period effective priorities (that is, priority values where **OrderPriority.PeriodEffective** is set to 'Y'). All demands that aren't satisfied within a given interval are given a higher priority than any demands in subsequent intervals. **Referenced table**: Calendar	Reference	
CoByProduct PlanningInterval	The calendar whose intervals are used in co-product and by-product calculations. The specified calendar defines an interval over which demands on a primary product are collected and sorted together, and any required planned orders on the primary product are created at the beginning of the period. For example, if set to a "weekly" calendar, then all required planned orders would be created at the beginning of the week. This setting can be used to help ensure that generated co-product or by-product supplies are available to satisfy demands over the duration of the period, and can thereby help to reduce potential excess resulting from co-product and by-product supplies. Note that a given primary product and all of its associated co-products and by-products should reference the same CoByProductPlanningInterval calendar. If excess on co-products and by-products is not a concern, or this sort of "pre-planning" logic is not required, then this calendar should be set to an "everyday" calendar. This calendar is ignored by parts not involved in any co-product or by-product configurations. For more information, see "Specify co-product planning calendar intervals" on page 1589. **Referenced table:** Calendar	Reference	
CommonPool	Specifies the common pool to be used (by calculations such as forecast consumption and netting). For example, if the control setting in the **MUEPoolNettingType.FlowToCommonPool** field is "NetCommon", then when a new planned order is required it should be planned in the specified pool. **Referenced table:** Pool	Reference	
ControlSet	The control set associated with this PlanningCalendars record. **Referenced table**: ControlSet	Reference	Yes

Table 7.42: PlanningCalendars (Mfg) fields

Field name	Description	Data type	Key
DataDate	The calendar to use (First entry) as the date when data was last updated. **Referenced table:** Calendar	Reference	
Description	A description of this set of calendars. An explanation of the code in the Value field. **Default value**: blank string	String	
ExpiryCalendar	The calendar whose intervals are used in material expiry calculations. For example, this calendar is used along with the value provided in the **Part.MinimumShelfLife** field (for calculating the EarliestExpiryDate on demands) and along with the value provided in the **PartSource.CTPIntervalsToExpiry** field (for calculating the ExpiryDate on supplies). Typically, this might be set to an "Everyday" calendar. **Referenced table:** Calendar	Reference	
Forecast Calendar	The "outer" calendar giving forecast interval dates (buckets in which forecast is received). For example, Month. **Referenced table:** Calendar	Reference	
OrderPoint Increase	The calendar giving the intervals used in calculations determining if a temporary increase in a part's order point threshold should be applied. For more information about order point calculations, see "Planned orders with order point" on page 1351. **Referenced table:** Calendar	Reference	

Table 7.42: PlanningCalendars (Mfg) fields

Field name	Description	Data type	Key
PercentSafety Interval	Identifies the calendar used in calculating safety stock when **SafetyStockQuantityRule** is either "PercentOfDemand" or "FractionOfDemand". That is, the bucketing upon which the calculation is done is based on a period which is "N" intervals in length. Where intervals is defined by the referenced calendar value and "N" is set to **Part.PercentSafetyIntervalCount**. For example, to have a safety value that was based on four weeks of demand, this field could be set reference a "Weekly" calendar and **Part.PercentSafetyIntervalCount** set to "4". **Referenced table:** Calendar **Note:** This field is only used by parts that have a Null reference in **Part.SafetyStockPolicy** (otherwise, if that reference is populated then the corresponding field on the **SafetyStockPolicy** record is used instead). Use of this field provides backward compatibility with versions prior to 2014.4.	Reference	
PeriodSupply DueCalendar	Defines the calendar giving valid planned order due dates when **PartType.DaysSupplyRule** = "ByPeriod", "ByPeriodWithPriority", "ByPeriodEnd", or "ByPeriodEndWithPriority". For example, if planned orders should be due at the beginning of the week, then set this to a weekly calendar. Or, if planned orders should be due on the first demand date in a given interval, set this to a work day calendar (such as, Part.PlanningCalendars.TimeUnits). **Referenced table**: Calendar **Note:** This field is ignored for parts that have days of supply logic enabled through a reference to the **DaysSupplyPolicy** table, and equivalent calendar references on that table are then used instead.	Reference	
PeriodSupply Interval	Defines the calendar intervals over which demands are accumulated when **PartType.DaysSupplyRule** = "ByPeriod", "ByPeriodEnd", "ByPeriodEndWithPriority" or "ByPeriodWithPriority". For example, demands might be accumulated weekly or monthly. **Referenced table**: Calendar **Note:** This field is ignored for parts that have days of supply logic enabled through a reference to the **DaysSupplyPolicy** table, and equivalent calendar references on that table are then used instead.	Reference	

Table 7.42: PlanningCalendars (Mfg) fields

Field name	Description	Data type	Key
RangeOf Coverage	The range of coverage profile for parts using this **PlanningCalendars** record. This profile is relevant only for those parts having a **PartType.SafetyStockQuantityRule** value of 'RangeOfCoverage'. For more information about range of coverage profiles, see "RangeOfCoverage table" on page 855. **Referenced table**: RangeOfCoverage **Note:** This field is only used by parts that have a Null reference in **Part.SafetyStockPolicy** (otherwise, if that reference is populated then the corresponding field on the **SafetyStockPolicy** record is used instead). Use of this field provides backward compatibility with versions prior to 2014.4.	Reference	
RunDate	The Calendar.Value that is used to determine the date the data is extracted from the enterprise data source. **Note:** The RunDate.FirstDate calculated field can be used to get this date for reporting purposes. This method of getting the run date into the system allows the date to be in a table that is extracted but can be specified by a part property. **Referenced table:** Calendar	Reference	
SecondCalendar	The "inner" calendar over which forecast values should be spread. For example, Week or Workday. **Referenced table:** Calendar	Reference	
Substitution Tolerance Calendar	The calendar used in substitute part calculations when determining how far out to search for existing supply of a primary part before looking for supply of a given substitute part (or, depending on configuration, how far out to search for supply of a given substitute part before looking for supply of the primary part). This value is used in conjunction with the **Part.SubstitutionTolerance** field. **Referenced table**: Calendar	Reference	
TimeFence Calendar	The calendar giving valid dates on which the demand Time Fence (DTF) will fall. Dates not on a calendar marker are rounded back to the next previous calendar marker. **Referenced table:** Calendar	Reference	
TimeUnits	The calendar giving valid dates for 'units of time' parameters (usually WorkDay). This allows for calculations to be based on shop time not on elapsed time. **Referenced table:** Calendar	Reference	

Table 7.42: PlanningCalendars (Mfg) fields

Field name	Description	Data type	Key
Value	The name (string value) for this set of Calendars. This value appears in the Part.PlanningCalendars_Value field. It is recommended that this value not contain spaces, special characters, or numbers. If any of these are used in the calendar name, then unexpected errors might occur when the calendar is used in query expressions that perform date arithmetic. **Default value**: blank string	String	Yes
Weekly	The name of the calendar to be used for weekly reporting on CRP Analysis as well as when calculating average days of supply for Inventory Analysis. **Referenced table:** Calendar	Reference	
Parts	Set of **Part** records that reference this PlanningCalendars value.	Set	
WorkCenters	Set of **WorkCenter** records that reference this PlanningCalendars value.	Set	

ProcessInstanceType table

The ProcessInstance type table contains configurable settings that define processing at the process instance level. For example, this table sets the calendar for the process instance.

Table 7.43: ProcessInstanceType (ProcOrch) fields

Field name	Description	Data type	Key
Calendar	The calendar used for calculating the start and finish dates in the process instance. **Referenced table:** Calendar	Reference	
ControlSet	The control set associated with this ProcessInstance record. **Referenced table:** ControlSet	Reference	Yes
Description	A description of this process instance type.	String	
RunDate	The calendar used in calculating the activity due dates. **Referenced table:** Calendar	Reference	
Value	A unique string identifier for this type of process instance.	String	Yes
ProcessInstances	A set of process instances.	Set	

ProductionWheelType table

The **ProductionWheelType** table defines the rules and values used to manage production wheels in RapidResponse.

This table was added in Service Update 1902.

Table 7.44: ProductionWheelType (Mfg) fields

Field name	Description	Data type	Key
ControlSet	A reference to the control set associated with this ProductionWheelType record. **Referenced table:** ControlSet	Reference	Yes
Description	A description of the production wheel type.	String	
UnsatisfiedSupplyRule	This setting determines what happens to unsatisfied supply quantities that are assigned to this cycle but cannot be built because the cycle has run out of constraint. Valid values are: **Defer**—Unsatisfied supply quantities are handled in the next cycle where the part can be built. **Ignore**—Unsatisfied supply quantities are ignored and not built in the cycle. Instead the supplies are assigned an available date of 'Future'.	String (Enum)	
UnusedConstraintRule	This setting determines how unused constraint is handled. Unused constraint is the constraint remaining after all supply quantities have been produced in the production wheel cycles where the minimum constraint consumption target has not been reached. Valid values are: **SatisfyFutureSupply**—Satisfy supplies that are normally produced in future cycles but are eligible to be built in the current cycle of this wheel. If there are still insufficient supplies to meet the minimum constraint consumption value for the production wheel, nothing else is built in this cycle. **Ignore**—If the constraint used in the current cycle does not meet the minimum constraint consumption value, ignore the value set for ProductionWheelConstraint.MinimumConstraintConsumption.	String (Enum)	
Value	A unique identifier for the production wheel type record.	String	Yes
ProductionWheels	A set of ProductionWheel records that reference this production wheel type.	Set	

ProjectType table

The **ProjectType** table contains configurable settings that define processing and calculations at the project level. For example, this table sets the project's working calendar, and specifies whether project dates are calculated from a given start date or finish date.

This table's records can be edited using the **Project Type** worksheet in the **Control Tables for Project Management** workbook.

Table 7.45: ProjectType (ProjMgmt) fields

Field name	Description	Data type	Key
AddActual DurationTo StartDate	When scheduling projects from finish, this setting indicates whether an in progress task's **StartDate**, or its **StartDate** + **ActualDuration**, is used when constraining a predecessor with either a "StartToStart" or "FinishToStart" relationship. Valid values are: • **N**—only the task's **StartDate** is used in determining predecessor dates. • **Y**—the task's **StartDate** + **ActualDuration** is used in determining predecessor dates. Additionally, if the task is complete, then its predecessor links are ignored. **Default value**: N	Boolean	
AllowNonZero Milestones	Specifies how the calculated duration on milestone tasks in the project is determined. Valid values are: • **N**—milestones always have their calculated duration set to 0 (zero). This is the default setting as milestones are used to mark important points in the project schedule and aren't typically assumed to have actual work associated with them. • **Y**—milestones have their duration calculated in the same way as normal tasks (based on actual work and resources associated with this task). With this setting, a milestone can have a duration other than 0 (zero). **Default value**: N	Boolean	

Table 7.45: ProjectType (ProjMgmt) fields

Field name	Description	Data type	Key
AllowTaskOnNonWorkingDay	Enables project tasks to potentially start or finish on non-working days if those days coincide with the start or finish dates on certain types of predecessor or successor tasks (and those tasks use different working calendars). Valid values • **N**—tasks are never allowed to start or finish on non-working days. • **Y**—tasks are allowed to start or finish on non-working days if any of the in projects scheduled from the start date, a task can finish on a non-working day if it has a "finish to finish" or "start to finish" relationship with a predecessor task. In projects scheduled from the finish date, a task can start on a non-working if a has a "start to start" or "start to finish" relationship with a successor task. **Default value**: N	Boolean	
ASAPBackwardTotalSlackRule	Indicates how total slack is calculated on tasks that have an "AsSoonAsPossible" constraint and belong to a project scheduled from finish. • **LateMinusEarly**—Total slack for such tasks is calculated as *min(LatestFinishDate - EarliestFinishDate, LatestStartDate - EarliestStartDate)*. • **Zero**—Total slack for such tasks always returns a value of 0. **Default value**: Zero	String (Enum)	
Bonus Accumulation Rule	If there are multiple **BonusScheduleByDate** or **BonusScheduleByInterval** records effective within the bonus period (between the project's **CalcFinishDate** and **BonusDate**), this setting determines how the bonus values on those records are used. Valid values are: • **Cumulative**—bonuses are calculated using the **OneTimeBonus** and **PerIntervalBonus** values defined on each effective entry in the bonus period and applied within their effective ranges only. With this setting there is the possibility for PerInterval bonuses that change over time along with multiple OneTime bonuses. • **FirstInterval**—bonuses are calculated using the **OneTimeBonus** and **PerIntervalBonus** values defined on the first effective entry within the bonus period and applied throughout the entire bonus period. This means either the **BonusScheduleByDate** record with the earliest **EffectiveOutDate** within the bonus period or the **BonusScheduleByInterval** with the highest **Interval** value within the bonus period is used. **Default value:** FirstInterval	String (Enum)	

Table 7.45: ProjectType (ProjMgmt) fields

Field name	Description	Data type	Key
BonusCalendar	The calendar used when calculating bonuses to be applied to a project. For example, should bonus revenue be earned on a daily or weekly basis. Referenced table: Calendar (this reference is nullable)	Reference	
BonusRule	Specifies the schedule, if any, to use for calculating project bonuses. This defines the one-time and per interval bonuses that can be earned and applied between the project's calculated finish date and bonus date. Valid values are: • **Date**—bonuses are applied based on dates and values defined in the **BonusScheduleByDate** table. The entries that apply to a given project are set through its **BonusSchedule** reference. • **Interval**—bonus values are applied based on bonus calendar intervals and values defined in the **BonusScheduleByInterval** table. The entries that apply to a given project are set through its **BonusSchedule** reference. • **None**—bonuses cannot be earned on projects of this type. **Default value:** None	String (Enum)	
Calendar	The calendar used when calculating start and finish dates on any tasks in the project for which the **TaskType.Calendar** reference is null. **Referenced table:** Calendar	Reference	
ControlSet	The control set associated with this **ProjectType** record. **Referenced table:** ControlSet	Reference	Yes
Description	A description of this project type.	String	
FreeSlack Calendar	Specifies the calendar used when calculating free slack (**Task.TotalSlack**) for tasks belonging to projects of this type. Valid values are: • **ProjectCalendar**—free slack is calculated using the project calendar (**ProjectType.Calendar**). • **TaskCalendar**— free slack is calculated using the task calendar (**TaskType.Calendar**). **Default value**: TaskCalendar	String (Enum)	

Table 7.45: ProjectType (ProjMgmt) fields

Field name	Description	Data type	Key
Penalty Accumulation Rule	In cases where there are multiple effective **PenaltyScheduleByInterval** or P**enaltyScheduleByDate** records found within the penalty window, this setting defines how the penalty costs from those effective records are apportioned to the applicable project or task. Valid values are: • **Cumulative**—penalty costs are calculated using the OneTime and PerInterval costs defined on each effective record found within the penalty window (based on effective date/interval). This setting allows for PerInterval costs that change over time along with multiple OneTime charges. • **LastInterval**—penalty costs are calculated using the OneTime and PerInterval costs defined on only the last effective record found within the penalty schedule (based on effective date/interval). This setting uses a constant PerInterval cost along with a single OneTime charge. **Default value:** LastInterval For more information about how this field is used, see "Penalties" on page 2191.	String (Enum)	
PenaltyCalendar	The calendar used when calculating penalties applied to a project. For example, should penalty costs be incurred on a daily or weekly basis. **Referenced table:** Calendar	Reference	
PenaltyRule	Specifies the schedule, if any, to use for calculating project penalty costs. This defines the one-time and per interval penalty costs that are applied between the project penalty date and finish date. Valid values are: • **Date**—penalty values are applied by dates defined in the **PenaltyScheduleByDate** table. The entries that apply to a given project are set through its **PenaltySchedule** reference. • **Interval**—penalty values are applied by calendar intervals defined in the **ProjectScheduleByInterval** table. The entries that apply to a given project are set through its **PenaltySchedule** reference. • **None**—penalties are not are calculated for projects of this type. **Default value:** None For more information about how this rule is used, see "Penalties" on page 2191.	String (Enum)	

Table 7.45: ProjectType (ProjMgmt) fields

Field name	Description	Data type	Key
Percent CompleteRule	For all fixed duration tasks in a project, this setting defines how the percentage complete on the task (**CalcPercentComplete**) is calculated. Valid values are: • **CalcDuration**—percentage complete on each fixed duration task is based on the amount of time the task is calculated to take as follows: *ActualDuration/CalcDuration* • **OriginalDuration**—percentage complete on each fixed duration task is based on the input value that originally specified the amount of time the task was expected to take as follows: *(Duration - CalcRemainingDuration)/Duration* **Default value**: CalcDuration **Note:** This field applies only when **Task.DurationType** is set to "FixedDuration". For all other **DurationType** settings, the task's percentage complete is always calculated based on **CalcDuration**.	String (Enum)	
PlanningRule	Indicates whether the project's current working date, as defined by the **Project.RunDate** field, should be considered when scheduling project tasks. For more information about project run dates, see "Project run dates" on page 2169. Valid values are: • **DateDriven**—the current working date is considered when scheduling tasks. Tasks that have not yet begun are never scheduled to start any earlier than **Project.RunDate** (typically, this setting is used to ensure tasks are not scheduled in the past). • **Standard**—the current working date is not considered when scheduling tasks. Tasks that have not yet started might be scheduled in advance of **Project.RunDate**. **Default value**: Standard **Note:** When this field is set to "DateDriven", any "FixedDuration" tasks in the project consider the task's **ActualStartDate**, **ActualFinishDate**, and/or **ExpectedFinishDate** values, along with the **RunDate** when calculating task durations. This can result in a **CalcDuration** result that differs from the input **Duration** value on the task.	String (Enum)	

Table 7.45: ProjectType (ProjMgmt) fields

Field name	Description	Data type	Key
ScheduleRule	Controls whether projects are scheduled backward from a given finish date, or scheduled forward from a given start date. Valid values are: • **FromFinish**—project dates are calculated backward from the project finish date. This option fixes the finish date and might be used to show late you can start a project. • **FromStart**—project dates are calculated forward from the project start date. This option fixes the start date and might be used to show when the project can finish. **Default value:** FromStart	String (Enum)	
TotalSlackRule	Specifies how total slack (**Task.TotalSlack**) is calculated for tasks belonging to projects of this type. Valid values are: • **Minimum**— Total slack is calculated as *min(LatestStartDate - EarliestStartDate, LatestFinishDate - EarliestFinishDate)* • **StartSlack**—Total slack is calculated as *LatestStartDate - Task.EarliestStartDate* • **FinishSlack**—Total slack is calculated as *LatestFinishDate - Task.EarliestFinishDate* **Default value:** Minimum	String (Enum)	
Value	A unique string identifier for this type of project. This value is referenced from the **Project.Type** field.	String	Yes
Projects	Set of **Project** records that reference this ProjectType value.	Set	

RangeOfCoverage table

This table is used to store range of coverage profiles. These profiles are used in safety stock calculations for parts where safety stock is meant to satisfy a number of days of the part's average daily demand (typically, within definable zones).

Profiles in this table are only applicable to parts whose effective **SafetyStockQuantityRule** setting, from either of the **SafetyStockPolicy** or **PartType** tables, is one of the following:

- **RangeOfCoverage**—safety stock is calculated to satisfy a number of days of the average daily demand within three distinct zones. Profiles in this table are used to determine how demands are collected for use in determining the average daily demand, the dates on which safety stock levels can be calculated, as well as the duration of the three coverage zones and the number of intervals of the average daily demand that safety stock should aim to satisfy in each zone.

  With this setting, all fields other than AverageRequirementIntervalLeadTimeCount are potentially applicable.
- **RangeOfCoverageLeadTime**—safety stock is calculated to satisfy the average daily demand over the part's lead time. Profiles in this table are used to determine how demands are collected for use

in determining the average daily demand as well as the dates on which safety stock levels can be calculated.

With this setting, all fields other than FirstZoneTarget, SecondZoneIntervalCount, SecondZoneTarget, and ThirdZoneTarget are potentially applicable.

- **TimePhasedRangeOfCoverage**— safety stock is calculated to satisfy a number of days of the average daily demand within any number of date-based zones. Profiles in this table are used to determine how demands are collected for use in determining the average daily demand as well as the dates on which safety stock levels can be calculated. Records in the **TimePhasedSafety** table are used to determine the start of each coverage zone as well as the number of days of the average daily requirement that the calculated safety stock levels should aim to satisfy within each of those zones.

  With this setting, all fields other than AverageRequirementIntervalLeadTimeCount, FirstZoneIntervalCount, FirstZoneTarget, SecondZoneIntercalCount, SecondZoneTarget, and ThirdZoneTarget are potentially applicable.

Notes:

- All RangeOfCoverage settings are also subject to optional upper and lower threshold limits that are defined in this table and used to determine whether a calculated change in the safety stock level is significant enough to warrant replacing the existing level.
- Certain range of coverage parameters can be overridden on a part by part basis using the **RangeOfCoveragePartOverride** table. For example, the fields used to set the duration over which demands are collected for use in calculating the average daily demand can be overridden. For more information, see "RangeOfCoveragePartOverride table" on page 509.
- **TimePhasedRangeOfCoverage** does not calculate dynamic safety stock for the last period of demand if there is no future demand. For example, it is expected for RapidResponse to recalculate the safety stock level in April 2016 and drop it to zero. Inserting a new TimePhasedSafety record for 08-01-0216 doesn't impact the calculation. Changing the date on the new record to 04-01-2016 when the last demand is due, drops the SS level to zero, as expected.
- For more information about range of coverage calculations, see "RangeOfCoverage calculations" on page 1409.

Table 7.46: RangeOfCoverage (Mfg) fields

Field name	Description	Data Type	Key
Average Requirement Interval	The name of the calendar in RapidResponse whose dates are used to set the intervals over which average daily demands are calculated. **Referenced table:** Calendar	Reference	
Average Requirement IntervalCount	The number of calendar units to consider demand from when calculating average daily demands. This value is used for each range of coverage zone.	Integer	

Table 7.46: RangeOfCoverage (Mfg) fields

Field name	Description	Data Type	Key
Average Requirement IntervalLead TimeCount	An optional parameter. It is applicable only when the applicable **SafetyStockQuantityRule** setting is "RangeOfCoverageLeadTime". It represents a factor of lead time that can be used to extend the period over which demands are accumulated when calculating the average daily demand. The value provided in this field is then multiplied by the longest lead time for the part expressed as a number of **AverageRequirementIntervals** (rounded up, if necessary). The result of that calculation is then added to the value in **AverageRequirementIntervalCount** to determine the total number of calendar units over which demands should be accumulated. **Default value**: 0	Integer	
Average Requirement IntervalOffset	A parameter allowing the average daily demand calculations to be offset a specified number of **AverageRequirementInterval** units from the start of the **RangeOfCoverageInterval**. For example, if **AverageRequirementInterval** is set to "Weekly" and this value is set to "3", then the average daily demand requirements will be calculated starting 3 weeks after the start of the **RangeOfCoverageInterval**. Default value: 0	Integer	
Average Requirement IntervalDuration Type	Indicates how days are interpreted when calculating the number of days in the average daily requirement window. Valid values are: • **TimeUnits**—Use the value in **Part.PlanningCalendars.TimeUnits** to calculate the number of days in the window. • **Everyday**—Use the standard everyday (Gregorian) calendar to calculate the number of days in the window. • **StandardDays**—Uses the product of **AverageRequirementIntervalCount** * **StandardDaysPerInterval** as the number of days in the window. **Default value**: TimeUnits	String (Enum)	
ControlSet	The control set associated with this RangeOfCoverage record. **Referenced table:** ControlSet	Reference	Yes
Description	A description of this range of coverage profile.	String	

Table 7.46: RangeOfCoverage (Mfg) fields

Field name	Description	Data Type	Key
FirstZoneInterval Count	The number of units in the calendar defined by **RangeOfCoverageInterval** that comprise the first range of coverage zone. If set to -1, this indicates that the first zone should extend to the end of the planning horizon. Typically, this is done when the zone target is set to the part's lead time (that is, where the applicable **SafetyStockQuantityRule** field is set to "RangeOfCoverageLeadTime"). This field is used only when the applicable **SafetyStockQuantityRule** field is set to either "RangeOfCoverage" or "RangeOfCoverageLeadTime'. **Note:** Past due demands are considered in this zone.	Integer	
FirstZoneTarget	The number of days of the average daily requirement to cover in the first zone. This field is used only when the applicable **SafetyStockQuantityRule** field is set to "RangeOfCoverage".	Quantity	
RangeOfCoverage Interval	The name of the calendar containing the dates on which safety stock levels can be calculated (applies to all range of coverage settings). For example, safety stock might be re-calculated weekly or monthly. This calendar also defines the dates used in calculating range of coverage zones when **SafetyStockQuantityRule** is set to "RangeOfCoverage". **Referenced table**: Calendar	Reference	
SecondZone IntervalCount	The number of units in the calendar defined by **RangeOfCoverageInterval** that comprise the second range of coverage zone. This field is used only when the applicable **SafetyStockQuantityRule** field is set to "RangeOfCoverage".	Integer	
SecondZoneTarget	The number of days of the average daily requirement to cover in the second zone. This field is used only when the applicable **SafetyStockQuantityRule** field is set to "RangeOfCoverage".	Quantity	
StandardDaysPer Interval	Used in calculating number of days in the average requirement window if **AverageRequirementIntervalDurationType** is set to "StandardDays". Otherwise, not used.	Integer	

Table 7.46: RangeOfCoverage (Mfg) fields

Field name	Description	Data Type	Key
ThirdZoneTarget	The number of days of the average daily requirement to cover in the third zone. This field is used only when the applicable **SafetyStockQuantityRule** field is set to "RangeOfCoverage".	Quantity	
ThresholdFactor Lower	A factor used along with the **Part.RangeOfCoverageBuffer field** to set the lower threshold limit for a given range of coverage interval as follows: • **LowerLimit** = Calculated SafetyStockLevel + (Part.RangeOfCoverageBuffer * ThresholdFactorLower) When the safety stock level is calculated for a range of coverage interval, this limit and an upper limit (using the **ThresholdFactorUpper** value) are also calculated. If the existing safety stock level (from the previous range of coverage interval) falls within these limits, then the new calculated level is discarded and the existing safety stock level remains effective. This is intended to avoid making minor changes to the safety stock level which might have only insignificant benefit. If, however, the existing safety stock level falls outside these limits, then the new calculated safety stock level becomes effective. **Default value:** 0	Quantity	
ThresholdFactor Upper	A factor used along with the **Part.RangeOfCoverageBuffer** field to set the upper threshold limit for a given range of coverage interval as follows: • **UpperLimit** = Calculated SafetyStockLevel + (Part.RangeOfCoverageBuffer * ThresholdFactorUpper) When the safety stock level is calculated for a given range of coverage interval, this limit and a lower limit (using the **ThresholdFactorLower** value) are also calculated. If the existing safety stock level (from the previous range of coverage interval) falls within these limits, then the new calculated level is discarded and the existing safety stock level remains effective. This is intended to avoid making minor changes to the safety stock level which might have only insignificant benefit. If, however, the existing safety stock level falls outside these limits, then the newly calculated safety stock level becomes effective. **Default value:** 0	Quantity	
Value	A unique identifier for this range of coverage profile. This field is referenced by the **SafetyStockPolicy** and **PlanningCalendars** table to determine the range of coverage profile applicable to a given part.	String	Yes

Table 7.46: RangeOfCoverage (Mfg) fields

Field name	Description	Data Type	Key
PlanningCalendars	Set of **PlanningCalendars** records that reference this RangeOfCoverage value.	Set	
SafetyStockPolicies	Set of **SafetyStockPolicy** records that reference this RangeOfCoverage value.	Set	

ResourceType table

The **ResourceType** table contains configurable settings that define processing and calculations at the resource level. For example, this table set the resource's working calendar, and specifies how standard and overtime costs are reported on resource loads.

This table's records can be edited using the **Resource Type** worksheet in the **Control Tables for Project Management** workbook included with RapidResponse.

Table 7.47: ResourceType (ProjMgmt) fields

Field name	Description	Data type	Key
Calendar	The calendar used in assigning resources and calculating loads against resources of this type. For example, this might typically be set to a workday calendar. **Referenced table:** Calendar	Reference	
ControlSet	The control set associated with this **ResourceType** record. **Referenced table:** ControlSet	Reference	Yes
CostAccrualRule	Specifies when standard and overtime costs are reported against resource loads generated from a given task. This impacts how values are reported in the **ResourceLoad.StandardCost** and **ResourceLoad.OvertimeCost** fields. Valid values are: • **Finish**—standard and overtime costs are reported on the last dates the resource is assigned to a given task. • **Prorated**—standard and overtime costs are reported on the actual dates they accrue during the duration of an assigned task. • **Start**—standard and overtime costs are reported against the finish date the resource is assigned to a given task. **Default value:** Prorated	String (Enum)	
ReportLimit	The number of Calendar periods after **Resource.DataDate** for which resource details are reported in the **ResourceDataByDate** tables.	Integer	

Table 7.47: ResourceType (ProjMgmt) fields

Field name	Description	Data type	Key
Value	A unique string identifier for this type of resource. This value is referenced from the **Resource.Type** field.	String	Yes
Resources	Set of **Resource** records that reference this ResourceType value.	Set	

SafetyStockItemType table

The **SafetyStockItemType** table contains control settings that define how safety stock items of a particular type are processed when generating safety stock recommendations. For example, fields in this table control item details such as whether the item is configured for time-phased safety stock calculations and how standard deviation of historical demands should be calculated.

Table 7.48: SafetyStockItemType (Mfg) fields

Field name	Description	Data type	Key
AsOfDate Calendar	Calendar used when collecting historical forecasts for use in calculating forecast error (typically, this might be a monthly calendar). Each series of historical forecast demands identified in the **HistoricalDemandSeries** table contains an **AsOfDate**, and only one series within a given **AsOfDateCalendar** is considered effective. To calculate forecast error for a given "Date", the **HistoricalDemandSeriesDetail** record (if any) that satisfies the following three conditions is used: 1. Series.AsOfDate + 0 'AsOfDateCalendar' = Date - ForecastLag 'AsOfDateCalendar' 2. Has the earliest Series.AsOfDate of all records satisfying the first condition. 3. Series.LastOnAsOfDate = 'Y'. **Referenced table:** Calendar (Nullable) **Note:** This field is only applicable on items where **StandardDeviationDemandRule** is set to "ForecastError".	Reference	
Average Demand Rule	Indicates how the average demand value used in calculating the safety stock level is determined. Valid values are: • **Mean**—the mean (average value) is used. This is the default and typically appropriate for demand that is normally distributed, however other options are available for cases where the demand is not normally distributed. • **Median**—the median (middle value) is used. • **Mode**—the mode (most frequent value) is used. If there are multiple values found for the mode, the smallest of these is used. **Default value:** Mean **Note:** This setting only applies to non time-phased calculations where **StandardDeviationDemandRule** is set to "StandardDeviation". Also, this setting only affects the average demand value used when calculating safety stock. Average historical and average future demand calculations always return a mean.	String (Enum)	

Table 7.48: SafetyStockItemType (Mfg) fields

Field name	Description	Data type	Key
BoundsRule	Indicates how minimum and maximum safety stock bounds, specified in the **SafetyStockTimePhased Bounds** table, are applied to this type of safety stock item or MEIO family. Valid values are: • **Ignore**—All maximum and minimum bounds specified in the **SafetyStockTimePhased Bounds** table are ignored. • **Quantity**—**MinimumQuantity** and **MaximumQuantity** values are used, while minimum and maximum days of supply are ignored. • **DaysOfSupply**— **MinimumDaysOfSupply** and **MaximumDaysOfSupply** values are used, while maximum and minimum quantities are ignored. **Default:** "Ignore" **Note:** This field was added in Version 2016.2.	String (Enum)	
ControlSet	The control set associated with this **SafetyStockItemType** record. **Referenced table:** ControlSet	Reference	Yes
CycleCalendar	The outer calendar used when an item is configured for time-phased safety stock calculations. The referenced calendar should typically define a full cycle for seasonal/trending data; for example, this might typically be a Yearly calendar. This calendar also applies when the Holt-Winters statistical model is used for estimating standard deviation of demand. **Referenced table**: Calendar (nullable) **Note:** The **CycleCalendar** and **IntervalsCalendar** settings determine the value to use for **SafetyStockItem.HistoricalIntervalCount**. This is to ensure that an adequate amount of historical demand and supply data is available for use in safety stock calculations. See "Define historical collection interval" on page 1956.	Reference	

Table 7.48: SafetyStockItemType (Mfg) fields

Field name	Description	Data type	Key
DemandOutlier ProcessingRule	Indicates how outliers found in historical data should be handled when processing safety stock items. The **Item.DemandOutlierThreshold** setting defines the number of standard deviations away from the mean an item quantity must be before it is considered an outlier (historical actuals are always first adjusted for any causal factors before checking/processing for outliers). Valid values are: • **Ignore**—historical actual quantities are left as is without any outlier adjustments. • **RemoveExcess**—outliers are removed from historical actuals by adjusting their quantities to the demand outlier threshold for the item. • **SmoothKeepExcess**—outlier quantities are adjusted by using parameters defined on the item to smooth the quantity above the outlier threshold over a number of intervals backward and then forward. If, after smoothing, any excess remains above the outlier threshold, it is left as is. • **SmoothRemoveExcess**—outlier quantities are adjusted by using parameters defined on the item to smooth the quantity above the outlier threshold over a number of intervals backward and then forward. If, after smoothing, any excess remains above the outlier threshold, that excess is reduced to the demand outlier threshold for the item. **Default value:** Ignore **Note:** This field is obsolete (as of Version 2016.2, Service Update 5). To achieve the same functionality, use the **RemoveDemandOutliers** field on the **SafetyStockItem** table.	String (Enum)	
Description	An optional description of this safety stock item type.	String	
ExcludePastDue Demands	Whether demands that are due prior to the period containing the RunDate are excluded from time-phased safety stock calculations. When this value is set to "N," the demands due prior to the interval containing the RunDate are included in time-phased safety stock calculations and they are considered as belonging to the interval containing the RunDate. **Default value**: N **Note:** This field was added in Version 2016.2, Service Update 7.	Boolean	

Table 7.48: SafetyStockItemType (Mfg) fields

Field name	Description	Data type	Key
ForecastBias AdjustmentRule	Indicates whether an automatic forecast bias adjustment is applied when calculating the standard deviation of forecast error. Forecast bias refers to systematic over or under forecasting. However, the item's specified service level can be used to automatically adjust for bias based on forecast error distribution. Valid values are: • **Ignore**—no adjustment for forecast bias is performed. • **Use**—forecast bias adjustment is performed. The adjusted standard deviation of forecast error is calculated using the following formula: $\frac{(1-\theta(\beta))/\theta(\beta)-1}{\tau\beta.\mathrm{d}} \times \mu$ where • θ is the probability distribution of forecast error points *Forecast / (Forecast + Actual*). • $\theta(\beta)$ is the quantile point corresponding to β in the theta distribution. • μ is the mean forecast error. • $\tau\beta.\mathrm{d}$ is a student-t distribution with cumulative density of β and d degrees of freedom (where d is the number of historical points). **Note:** This field is only applicable on items where **StandardDeviationDemandRule** is set to "ForecastError". **Note:** When forecast error pooling is enabled, the forecast bias adjustment rule is ignored.	String (Enum)	

Table 7.48: SafetyStockItemType (Mfg) fields

Field name	Description	Data type	Key
ForecastError Outlier ProcessingRule	Indicates how outliers are treated in measures of forecast error. Outliers are detected using the **ForecastErrorOutlierThreshold** value specified on the **SafetyStockItem** record (this specifies the number of standard deviations away from the mean that a forecast error point must be in order to be considered an outlier). Applicable on items where **StandardDeviationDemandRule** is set to "ForecastError". Valid values are: • **Ignore**—forecast error outliers are included when calculating the standard deviation of forecast error. • **Remove**—forecast error outliers are excluded when calculating the standard deviation of forecast error. • **RemoveExcess**—forecast error outliers are reduced to the outlier threshold defined as *Mean of ForecastError +- ForecastErrorOutlierThreshold * StandardDeviation of ForecastError* **Note:** This field is obsolete (as of Version 2016.2, Service Update 5). To achieve the same functionality, use the **RemoveDemandOutliers** field on the **SafetyStockItem** table.	String (Enum)	
IntervalsCalendar	Defines the calendar used in standard calculations for the safety stock item. For example, historical demands are bucketed, and average demand calculations are expressed, in terms of this calendar. This field also sets the calendar used for lead time values in cases where the **LeadTimeCalendar** is left Null. **Referenced table:** Calendar (nullable) **Note:** An everyday calendar is assumed if this field is not populated. **Note:** The **IntervalsCalendar** and **CycleCalendar** settings determine the value to use for **SafetyStockItem.HistoricalIntervalCount**. This is to ensure that an adequate amount of historical demand and supply data is available for use in safety stock calculations. See "Define historical collection interval" on page 1956.	Reference	
IntervalsPer Period	The number of **IntervalCalendar** units within a **PeriodCalendar**. When statistical models are used to determine the standard deviation of demand based on forecast error variability, this is used to convert results calculated in terms of the **PeriodCalendar** to units of the **IntervalCalendar**. For example, this might involve converting a monthly forecast error to daily forecast error. Default value: 1	Quantity	

Table 7.48: SafetyStockItemType (Mfg) fields

Field name	Description	Data type	Key
LeadTime Calendar	Defines the calendar used in lead time calculations for the safety stock item. For example, if using variable lead time in safety stock calculations, then historical lead times are calculated in terms of this calendar (the difference between the historical order date and supply date is expressed in units of this calendar). The input lead time specified on the **SafetyStockItem** record should also be specified in units of this calendar. If a valid calendar reference is not provided, then the **IntervalsCalendar** is used by default. In cases where **UseRollingLeadTimeCalendar** is set to "Y", then **LeadTimeCalendar** will always be ignored even if populated and **IntervalsCalendar** used instead. If history is monthly bucket and lead time is daily, then there are not enough points to meaningfully calculate rolling lead time demand. **Referenced table:** Calendar (Nullable) **Note:** LeadTimeCalendar only applies to SEIP.	Reference	
LeadTimePer Interval	Specifies the number of **LeadTimeCalendar** intervals within an **IntervalsCalendar**. For example, if **LeadTimeCalendar** is "Everyday" and **IntervalsCalendar** is "Week", this might be set to "7". The value in this field is used to ensure the standard deviation of demand parameter used in the calculation of safety stock is expressed in terms of the item's lead time calendar. **Note: SafetyStockItemType.LeadTimePerInterval** should never be less than 1 and should not have larger intervals than the **IntervalsCalendar**. When **SafetyStockItemType.LeadTimePerInterval** is less than 1, the value will automatically be treated as 1; thus resulting in an incorrect calculation of **SafetyStockResult.SafetyStock**. **Note:** For an example of how this field is used, see "Example 3: Fixed lead time (with forecast error)" on page 1972.	Quantity	

Table 7.48: SafetyStockItemType (Mfg) fields

Field name	Description	Data type	Key
MEIODemand Historicals PropagationRule	Enables forecast error pooling. The value of this field only matters if: • the part on the **SafetyStockItem** is the head of an MEIO Family • **TimePhasedProcessingRule** is either **Ignore**, **DaysOfSupplyBackward** or **DaysOfSupplyForward** • **StandardDeviationDemandRule** is set to **ForecastError** Valid values are: • **Use**—enables forecast error pooling for the entire MEIO family. In this case, forecast error pooling is used on all customer facing stages in this MEIO family, regardless of what was set on the **SafetyStockItemType.StandardDeviationDemandRule** . • **Ignore**—forecast error pooling is disabled for the entire MEIO family. **Default value:** Ignore **Note:** This field was added in Version 2016.2.	String (Enum)	

Table 7.48: SafetyStockItemType (Mfg) fields

Field name	Description	Data type	Key
NonStationary DemandRule	Specifies how the standard deviation of historical demands is calculated for those items where **TimePhasedProcessingRule** is set to "Use" (applies to both single and multi-echelon items). The value calculated based on this setting is then used as a parameter when generating time phased safety stock recommendations. Valid values are: • **Decomposition**—A time series decomposition method is used to calculate standard deviation on historical demands within each period after removing trend from the data. This method is typically appropriate when there is more than two cycles (typically, years) of historical demand data available. • **HoltWinters**—HoltWinters seasonal forecasting method is used to calculate standard deviation of forecast error within each period. This method is typically appropriate when there is more than two cycles (typically, years) of historical data available. • **Manual**—Average and standard deviation of historical demands within each period is set to the values that have been provided in the **TimePhasedDemandParameterSet** table. This method is typically appropriate when there is little historical demand data available (less than a full cycle or year). • **Simple**—Standard or simple calculation of standard deviation is performed on bucketed historical demands within each period. This method is typically appropriate when there is between one and two cycles (typically, years) of historical demand data available. **Default Value**: Simple **Note:** If **TimePhasedProcessingRule** is set to "Ignore" or "DaysOfSupplyBackward" or "DaysOfSupplyForward", then the **StandardDeviationDemandRule** field applies instead.	String (Enum)	
PeriodCalendar	The inner calendar applicable if the item is configured for time-phased safety stock calculations. The referenced calendar should define a period or season within the cycle; for example, if the CycleCalendar is Year, then this might typically reference a Quarter or Month calendar. This calendar also applies when using statistical models (such as, exponential smoothing or Holt-Winters) to base the standard deviation of demand on forecast error variability. It is the calendar by which historical demand data should be bucketed when fitting data to these models (typically, monthly or quarterly calendar might be used). **Referenced table:** Calendar (nullable)	Reference	

Table 7.48: SafetyStockItemType (Mfg) fields

Field name	Description	Data type	Key
PeriodsPerCycle	The number of **PeriodCalendar** units within a **CycleCalendar**. For example, four quarters might make up a yearly cycle. This field applies to time-phased safety stock calculations, as well as when using the Holt-Winters method to calculate standard deviation of demand based on forecast error variability.	Integer	
ServiceLevelRule	Determines the measure of customer satisfaction that the recommended safety stock level is meant to achieve. This setting controls how the **ServiceLevel** value specified on the **SafetyStockItem** record is interpreted. Service levels are entered as percent values and, together with the setting in this field, determine the corresponding z-value or service factor (used as a multiplier when calculating safety stock levels). Valid values are: • **Cycle**—An event based service level that sets the probability of not stocking out when filling a demand within lead time. This refers to an alpha or type1 service level. • **FillRate**—A quantity based service level that sets the overall percentage of demand which should be satisfied on time. This refers to a beta or type2 service level. If using this option, the **MinimumOrderQuantity** field on the **SafetyStockItem** record should also be set for use in determining the z-value for a given fill rate service level. **Default value**: Cycle **Note:** This field applies only to single-echelon calculations. Multi-echelon safety stock items always use a Cycle fill rate regardless of the setting in this field.	String (Enum)	

Table 7.48: SafetyStockItemType (Mfg) fields

Field name	Description	Data type	Key
Standard Deviation DemandRule	Specifies how the parameter representing standard deviation of historical demands is determined for safety stock items that are not configured for time phased calculations (if **TimePhasedProcessingRule** is set to "Use", then the **NonStationaryDemandRule** field applies instead). By default, the standard deviation is calculated based on historical actuals. However, standard deviation can also be calculated based on historical forecast error (difference between historical forecast and actuals). Additionally, various statistical models can be fitted for use in calculating and returning forecast error instead. If using these statistical models, a Period calendar might typically need to be specified. Valid values are: • **CrostonsMethod**—Croston's method is used to return forecast error variability (appropriate for lumpy or intermittent data). • **DoubleExponentialSmoothing**—double exponential smoothing is used to return forecast error variability (appropriate for stable data with a trend). • **ExponentialSmoothing**—exponential smoothing is used to return forecast error variability (appropriate for stable data with no trend). • **ForecastError**—standard deviation from forecast error is returned. Forecast error is calculated by comparing historical forecasts (from the HistoricalDemandSeriesDetail table) against historical actuals (from the HistoricalDemandActual table). The HistoricalDemandCategory and HistoricalForecastCategory reference fields on the SafetyStockItem record indicate the historical actual and historical forecast categories to use respectively. • **HoltWintersMethod**—Holt-Winters method is used to return forecast error variability (appropriate for data that is seasonal in nature). • **LinearRegression**—a simple linear regression is used to return forecast error variability. • **Manual**—standard deviation of historical demand and average historical demand are each set to values provided on the **SafetyStockItem** record (in the **StandardDeviationDemand** and **AverageDemand** fields respectively). This method is intended for cases where there is little or no historical demand data available, but the related demand parameters are known or estimated through some other means. • **StandardDeviation**—standard deviation from demands in the **HistoricalDemandActual** table is returned. Historical demands used for the item are those belonging in the category referenced by	String (Enum)	

Table 7.48: SafetyStockItemType (Mfg) fields

Field name	Description	Data type	Key
	HistoricalDemandCategory on the **SafetyStockItem** record. **Default value**: StandardDeviation		
Supply VariabilityRule	Indicates if variability of historical supply lead times should be considered when calculating recommendations for safety stock levels and reorder point. If variability of historical supply lead time is to be considered, the required parameters can be either manually provided or calculated based on historical supply data. Note that variability of supply is only applicable when calculating stationary (non time-phased) safety stock for single-echelon items. Valid values are: • **Ignore**—Variability of historical supply lead times is ignored. A constant lead time, as provided on the safety stock item, is assumed. No records are reported for the item in the **SafetyStockHistoricalSupply** table. • **Manual**—Variability of historical supply lead time is considered in safety stock and reorder point calculations. Standard deviation of lead time and average lead time are each set to values provided on the **SafetyStockItem** record (in the **StandardDeviationLeadTime** and **LeadTime** fields respectively). Records are not generated for the item in the **SafetyStockHistoricalSupply** table. • **Use**—Variability of historical supply lead time is considered in safety stock and reorder point calculations. Historical lead times for supplies are calculated using the **Date** and **OrderDate** fields on the **HistoricalSupplyActual** table (both of these fields must be populated). Records are generated for the item in the **SafetyStockHistoricalSupply** table for each supply within the historical collection interval. **Default value:** Ignore	String (Enum)	

Table 7.48: SafetyStockItemType (Mfg) fields

Field name	Description	Data type	Key
TimePhased ProcessingRule	Specifies whether the item is configured for time-phased safety stock calculations. Time-phased safety stock can be calculated for both single and multi-echelon items. The setting in this field also determines how the standard deviation of demand parameter is calculated. When set to "Use", the standard deviation of demand is calculated based on the setting in the **NonStationaryDemandRule** field. Otherwise, the standard deviation of demand is calculated based on the setting in the **StandardDeviationDemandRule** field. Valid values: • **DaysOfSupplyBackward**—A single safety stock value is initially calculated and then expressed as a number of intervals of the part's average historical demand. Time-phased safety stock values are then generated based on the total amount of future and/or historical demand found when looking back that number of intervals from a given point. • **DaysOfSupplyForward**— A single safety stock value is initially calculated and then expressed as a number of intervals of the part's average historical demand. Time-phased safety stock values are then generated based on the total amount of future demand found when looking ahead that number of intervals from a given point. • **Ignore**—Time-phased safety stock calculations are disabled for this item. A single safety stock level is calculated for the item and reported on RunDate. • **Use**—Time-phased safety stock calculations are enabled for this item with safety stock reported on RunDate as well as each subsequent period in which a new value applies. Appropriate cycle and period calendars should be defined when using this setting, with the standard deviation of demand and average historical demand parameters calculated for each period. Note also that fixed lead time is always assumed (variable lead time is not supported in time-phased calculations). **Default value:** Ignore. **Note:** For an example of how time-phased safety stock is calculated, see "Time-phased safety stock" on page 1977. For an example of how safety stock is calculated using days of supply, see "Days of supply and safety stock" on page 1981.	String (Enum)	

Table 7.48: SafetyStockItemType (Mfg) fields

Field name	Description	Data type	Key
UseRollingLead TimeDemand	Specifies which of rolling lead time demands or bucketed demand quantities are used to determine the average demand and standard deviation for use in calculating safety stock. Valid values are: • **N**—average demand and standard deviation calculations use bucketed demand quantities based on the safety stock item calendar (for example, daily buckets). Based on the setting in the **StandardDeviationDemandRule** field, either the standard deviation or standard error calculated for these bucketed demands is used and multiplied by the square root of lead time. • **Y**—average demand and standard deviation calculations use rolling lead time demand quantities. Based on the setting in the **StandardDeviationDemandRule** field, either the standard deviation or standard error calculated for these rolling lead-time demands is used. **Default value:** N	Boolean	
Value	A unique string identifier for this type of safety stock item. This value is referenced from the **SafetyStockItem.Type** field.	String	Yes

SafetyStockPolicy table

The **SafetyStockPolicy** table contains control settings specifying how netting calculations determine or maintain safety stock levels in RapidResponse.

This table is referenced from the **Part.SafetyStockPolicy** field, and is used by all parts that have that reference populated. Otherwise, if a part's **SafetyStockPolicy** reference is Null, then identical control settings on the **PartType** and **PlanningCalendars** tables are used instead. However, use of the **SafetyStockPolicy** table for managing safety stock controls is recommended as it allows for easier modeling of safety stock settings without the need to maintain additional **PartType** records (which hold many other planning policies). For example, a number of different combinations of safety stock settings might be required in what-if scenarios used to analyze recommendations generated by inventory management solutions in RapidResponse.

If upgrading from a version of RapidResponse earlier than 2014.4, a workbook is available that can create and then reference values in this table based on a part's existing **PartType** and **PlanningCalendars** settings. For more information, see "Moving safety stock settings to the SafetyStockPolicy table" on page 2409.

Table 7.49: SafetyStockPolicy (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this **SafetyStockPolicy** record. **Referenced table:** ControlSet	Reference	Yes
CTPHoldRule	Indicates whether priority on safety stock is considered in capable-to-promise logic. For example, priority can be used to ensure minimum safety stock requirements are maintained. Thus, when all demands cannot be satisfied on time, allotments of supply to demand can be held to ensure the higher priority safety stock level is maintained (or minimally violated if is not possible to always maintain it). Valid values are • **Ignore**— Priority on safety stock is not considered in capable-to-promise logic. Actual demands are always preferred to safety stock (regardless of priority), and supply allotments will never be held to ensure safety stock levels are respected. This setting corresponds to how safety stock was always treated in capable-to-promise logic prior to Version 2016.2, Service Update 18. • **Use**— Priority in capable-to-promise logic is considered in capable-to-promise logic. Maintaining safety stock is preferred to satisfying actual demands of a lower priority level, while actual demands of the same or higher priority are preferred to safety stock. As necessary, allotments of supply to (lower priority) actual demands can be held to ensure the safety stock level is maintained. Details of these held allotments are then reported in the **HoldStartDate** and **HoldEndDate** fields on the **SupplyDemand** and **CTPActivity** tables. **Default value:** Ignore **NOTE**: This field was added in Version 2016.2, Service Update 18. For more information about how priorities on safety stock are used in capable-to-promise logic, see "Priority and safety stock holds in CTP" on page 1780.	String (Enum	

Table 7.49: SafetyStockPolicy (Mfg) fields

Field name	Description	Data type	Key
DemandTransformationRule	Specifies whether demand transformations are applied when safety stock requirements are present. This setting determines whether planned supplies take their priorities from the driver requirement (including safety stock) that led to their creation, or from the real demand that the supply is assumed to satisfy based on demand due date sequence. Valid values are: • **FirstInFirstOut**—Demand transformations are applied, and supplies take their priority from the real demand they are assumed to satisfy based on due date sequence. Thus supply created to satisfy safety stock requirements is given the priority of the next real demand it would ultimately satisfy. Such supplies might also be split if they are seen to satisfy multiple subsequent real demands of different priorities. Similarly, because real demands can be covered by supply created to satisfy safety stock, the supplies created to satisfy those real demands will then take their priority from subsequent/later demands. This setting is intended to ensure that planned supplies throughout the structure reflect the priority of the demands they ultimately satisfy, and prevent situations were higher priority demands might end up late because they are satisfied by released safety stock supply. When there are no real demands, the part's default priority is used. • **Ignore**—Demand transformation are not applied, and supplies take their priority from the driver demand or safety stock requirement that led to their creation. Thus, supply generated to satisfy safety stock requirements is always assigned the part's default priority (typically, this will be a lower priority). In cases where the safety stock level is reduced, this lower priority planned supply can then be consumed by real demands. Note that if these demands are of a higher priority, their priority might not be fully respected and/or propagated down to component supplies in the structure which can result in higher priority demands being satisfied late. This setting corresponds to how safety stock logic was always applied prior to Service Update 1905. **Default value:** Ignore **Note:** Supplies for parts that have a **CommitLevel** setting of "Medium" or "Low" are always planned using the default priority regardless of the setting in this field. **Note**: This field was added in Service Update 1905. For more information about the impact of this setting, see "Safety stock and priority adjustments" on page 1773.	String (Enum)	
Description	A description of this safety stock policy.	String	

Table 7.49: SafetyStockPolicy (Mfg) fields

Field name	Description	Data type	Key
ExpiryRule	Specifies when expiring supply allocated to safety stock should be replenished. Valid values are: • **AtExpiry**: A new order is planned for when the safety stock supply will expire (at expiry date). • **AtPartMSL**: A new order is planned for when the safety stock supply will no longer be able to to satisfy demands in respect of the part's shelf life requirements (at expiry date less minimum shelf life). **Default value:** AtExpiry **Note:** This field was added in Version 2016.2	String (Enum)	
OrderPointDate Rule	Indicates the date on which scheduled supply (scheduled receipts, inventory transfers, and supply allocations) for order point parts should be included when calculating whether the threshold for creating new planned orders has been crossed. Valid values are: • **Due**—Scheduled supply is considered as of its ReschedDate (calculated due date). As a result, supply that is already started, but not yet due, is ignored when determining if the order point threshold has been reached. Planned orders might therefore be created to cover this timing gap. • **Start**— Scheduled supply is considered as of its CalcStartDate (calculated start date). As a result, the order point threshold will not be crossed if a sufficient quantity is available in a started, but not yet due, scheduled supply. This is the recommended value. **Default value**: Due	String (Enum)	

Table 7.49: SafetyStockPolicy (Mfg) fields

Field name	Description	Data type	Key
OrderPoint Increase	Indicates if a temporary increase in a part's order point threshold should be considered to guard against near-term spikes in demand that might push inventory below zero before more supply can be planned. This setting is only applicable to order point parts (that is, parts where **SafetyStockRule** is set to either "OrderPointAverage", "OrderPointOver", or "OrderPointUnder"). Additionally, this setting relies on the part's **PlanningCalendars.OrderPointIncrease** setting which specifies a calendar whose intervals are used, starting from the RunDate, to look for demand within the part's lead time. Valid values are: • **Calculate**— an increase in the order point is considered for each **PlanningCalendars.OrderPointIncrease** interval where there is demand within lead time. If the demand within lead time (plus any additional demand within the OrderPointIncrease interval) exceeds the effective order point, then the amount it exceeds it by is temporarily added to the order point. This increase is effective until the next OrderPointIncrease interval. • **Ignore**—order point threshold is never inflated to cover spikes in demand that will consume supply before it can be replenished. • **Sum**— an increase in the order point is considered for each **PlanningCalendars.OrderPointIncrease** interval where there is either demand within lead time or a value is provided in the **TimePhasedSafety** table. If the demand within lead time (plus any additional demand within the OrderPointIncrease interval) exceeds the effective order point, then the amount it exceeds it by is temporarily added to the order point. As well, if an effective record is found in the **TimePhased Safety** table, then its quantity is also added to the effective order point (if multiple **TimePhasedSafety** entries are found in the interval then the one with the largest **Quantity** is used). The total increase is effective until the next OrderPointIncrease interval. Note that if **SafetyStockQuantity** is "TimePhasedQuantity" or "TimePhasedQuantityToLatest", then this option and **Calculate** are the same. • **SumOffset**— identical to **Sum**, except that increases are never performed in the first interval (containing the SafetyStockDate). **Default value:** Ignore	String (Enum)	

Table 7.49: SafetyStockPolicy (Mfg) fields

Field name	Description	Data type	Key
PercentSafety Interval	Identifies the calendar used in calculating safety stock when **SafetyStockQuantityRule** is either "PercentOfDemand" or "FractionOfDemand". That is, the bucketing upon which the calculation is done is based on a period which is "N" intervals in length. Where intervals is defined by the referenced calendar value and "N" is set to **Part.PercentSafetyIntervalCount**. For example, to have a safety value that was based on four weeks of demand, this field could be set reference a "Weekly" calendar and **Part.PercentSafetyIntervalCount** set to "4". **Referenced table:** Calendar (Nullable) **Note:** If this reference is Null, then the part's **PlanningCalendars**.**PercentSafetyInterval** reference is used instead.	Reference	
RangeOf Coverage	A reference to range of coverage profile for parts using this policy. This profile is relevant only when **SafetyStockQuantityRule** is set to 'RangeOfCoverage'. **Referenced table:** RangeOfCoverage **Note:** If this reference is Null, then the part's **PlanningCalendars.RangeOfCoverage** reference is used instead.	Reference	

Table 7.49: SafetyStockPolicy (Mfg) fields

Field name	Description	Data type	Key
SafetyStockDate Rule	Specifies the date on which to plan for safety stock for parts using this policy. Valid values are: • **FirstDemand**—maintain safety stock level as of the date of the earliest demand record. The **PlannedOrder.DueDate** will be the date of the first demand (**Part.SafetyLeadTime** + **PartSource.SafetyLeadTime**). • **FirstDemandOrLeadTime**—if the part has demands, then a planned order is generated to cover safety stock at the date of the first demand. If the part has no demands, then a planned order is generated to cover safety stock at either **RunDate + LeadTime** (if **OrderPolicy.OrderGenerationRule** is 'AnyTime' or 'AfterRunDate'), or at the later of **RunDat**e + **LeadTime** or **PTFDate** (if **OrderPolicy.OrderGenerationRule** is 'AfterPTF'). • **FirstDemandOrRunDate**—if the part has demands, then a planned order is generated to cover safety stock at the date of the first demand. If the part has no demands, then a planned order is generated to cover safety stock at either **RunDate** (if **OrderPolicy.OrderGenerationRule** is 'AnyTime' or 'AfterRunDate'), or at **PTFDate** if **OrderPolicy.OrderGenerationRule** is 'AfterPTF'). • **FirstDemandOrPast**—if the part has demands, then generate a planned order to maintain safety stock at the date of the first demand. If the part has no demands, then a planned order is generated to cover safety stock at either **Past** if **OrderPolicy.GenerationRule** is 'AnyTime', or at **RunDate** if **OrderPolicy.GenerationRule** is 'AfterRunDate', or at **PTFDate** if **OrderPolicy.OrderGenerationRule** is 'AfterPTF'. • **LeadTime**—maintain safety stock level after RunDate (**Part.PlanningCalendars.RunDate.Value**) + **PartSource.FixedLeadTime** + **Part.LeadTimeAdjust** + **PartSource.Source.TransitTime** + (**PartSource.VariableLeadTime** * **Part.SafetyStockQty**). Additionally, if either or both of **Part.SafetyLeadTime** or **PartSource.SafetyLeadTime** are greater than zero (0) then they are added to the above in determining **PlannedOrder.DemandDate**. This is meant to achieve a realistic **PlannedOrder.StartDate**. However, lot sizing or other demands might make the start date earlier in the presence of **PartSource.VarLeadTime**. Additionally, **OnHand** records for the part may make the actual **PlannedOrder.Quantity** less and thus the **PlannedOrder.StartDate** later. • **LeadTimeReportUnplanned**—similar to the "LeadTime" option in that safety stock is only maintained/planned after	String (Enum)	

Table 7.49: SafetyStockPolicy (Mfg) fields

Field name	Description	Data type	Key
	RunDate plus applicable lead times. However, with this setting safety stock levels are still calculated, for reporting purposes only, within lead time. These unplanned safety stock levels are reported in the **Activity** table with a **Type** value of "UnplannedSafety". • **Past**—safety stock can be maintained at any time even if it means placing orders in the past. • **Rundate**—safety stock can be maintained as of RunDate. **Default value:** LeadTime **Note:** When using the "LeadTime" or "LeadTimeReportUnplanned' settings, the lead time from the part's primary part source is used in determining the date from when safety stock can be planned. For example, if a secondary part source has shorter lead time and is used to satisfy a safety stock demand, it still cannot plan it any earlier than **RunDate** plus lead time from the primary part source. **Note:** Ordering policies or planning time fence may override any of the values described above. **Note:** This field was modified in Version 2016.2, Service Update 8.		
SafetyDays Calendar	When using a **SafetyStockQuantityRule** setting of either "TimePhasedSafetyDaysMaximum" or "TimePhasedSafetyDaysMaximum", this specifies the calendar whose intervals are used in collecting demands for use in calculating the safety stock level (that is, the calendar in which the value in **TimePhasedSafety.Days** is expressed). If this reference is left Null, then an Everyday calendar is assumed. Referenced table: Calendar (Nullable) **Note:** This field was added in Version 2016.2.	Reference	

Table 7.49: SafetyStockPolicy (Mfg) fields

Field name	Description	Data type	Key
SafetyDays Dependent DemandUsage	When using a **SafetyStockQuantityRule** setting of either "TimePhasedDaysMaximum" or "TimePhasedDaysTotal", this field specifies the type of dependent demands that are collected and summed for use in calculating safety stock levels. This setting does not affect independent demands. Valid values are: • **All**—All types of dependent demands are used in the safety stock calculation. • **MakeOnly**—Dependent demands from "make" sources are used in the safety stock calculation. • **None**—Dependent demands are excluded from use in the safety stock calculation. • **TransferOnly**—Dependent demands from "transfer" sources are in the safety stock calculation. **Default value**: All **Note:** This field was added in Version 2016.2. **Note:** In addition to this setting, specific demand types can be included or excluded from use in safety stock calculations based on the **DemandType.SafetyStockDemandUsage** setting. That is, only dependent demands that reference a **SafetyStockDemandUsage** setting of "Use" are eligible for use in calculating dynamic safety stock levels (regardless of the setting in this field).	String (Enum)	

Table 7.49: SafetyStockPolicy (Mfg) fields

Field name	Description	Data type	Key
SafetyStock QuantityRule	Specifies how the safety stock level is determined for parts using this policy. Valid values are: • **FixedQuantity**—safety stock is set to the fixed input value provided in **Part.SafetyStockQty**. • **FractionOfDemand**—safety stock levels are dynamically calculated based using the value in Part.PercentSafetyPercent which is assumed to represent a fraction (for example, .1 means 10%) of total demand per defined interval. Demand intervals are calculated (beginning from the maximum of the **Part.PlanningCalendar.RunDate** or safety stock date) using the value specified in **PercentSafety Interval**. The number of intervals to use is calculated using the value in **Part.PercentSafetyIntervalCount**. All demands during this interval are summed and the **Part.PercentSafetyPercent** is applied against the total demand quantity resulting in a dynamic safety stock quantity for that interval. • **PercentOfDemand**—safety stock levels are calculated the same as "FractionOfDemand", except that the **Part.PercentSafetyPercent** value is interpreted as a percentage (for example, 10 means 10%). • **RangeOfCoverage**—safety stock levels are calculated to satisfy a specified number of days of a part's average daily requirements, and can be configured for three distinct date zones. All parameters used to calculate these safety stock levels are configured through range of coverage profiles in the **RangeOfCoverage** table. If this option is selected for a part, the part's range of coverage profile is taken from the value referenced in the **RangeOfCoverage** field. For more information, see "RangeOfCoverage table" on page 855. • **RangeOfCoverageLeadTime**—safety stock levels are calculated to satisfy the part's average daily requirement over its lead time plus an optional buffer quantity. Most parameters used to calculate these safety stock levels are configured through range of coverage profiles in the **RangeOfCoverage** table. However, with this setting only the first zone is active and the average daily requirement is multiplied by lead time rather than the FirstZoneTarget value. • **TimePhasedQuantity**—safety stock levels change over time. The **TimePhasedSafety** table must be populated with the following fields: Part, Site, Date (earliest date this safety stock quantity is applicable), and Quantity. For example, a Quantity of 5 is effective beginning 01-01-15 and a Quantity of 10 is effective beginning 06-01-15. This means that the safety stock of 5 is no longer effective as of 05-31-15. For more information, see	String (Enum)	

Table 7.49: SafetyStockPolicy (Mfg) fields

Field name	Description	Data type	Key
	"TimePhasedSafety table" on page 655. This setting is identical to "TimePhasedQuantityToLatest" except in cases where the part's safety stock level decreases after the last demand. • **TimePhasedQuantityToLatest**—This setting is identical to "TimePhasedQuantity" except in cases where the safety stock level decreases after the last demand for the part. If the safety stock level decreases after the last demand for the part, then the quantity of the last planned order will be reduced to ensure the resulting inventory level meets the latest value defined in the **TimePhasedSafety** table. If using lot sizing, the **OrderPolicy.LotSizeLastOrder** field should be set to "N" to ensure this behavior. Otherwise, if **LotSizeLastOrder** is set to "Y", then the last planned order will only get as close as it can to the latest defined safety stock level while still respecting all lot-sizing rules. • **TimePhasedRangeOfCoverage**—safety stock levels are calculated to satisfy a specified number of days of a part's average daily demand, and are configurable for any number of zones. When using this setting, records in the **TimePhasedSafety** table are used to define the start of each range of coverage zone as well as the number of days of the part's average daily requirement that safety stock should cover in each of those zones. Additionally, parameters from the **RangeOfCoverage** table are used to specify how demands are collected for use in calculating the average daily requirement, as well to set the calendar whose intervals can be used to generate new safety stock levels. • **TimePhasedSafetyDaysMaximum**—safety stock levels are calculated daily. Based on effective values in the **TimePhasedSafety** table, safety stock is set to the maximum of demand collected over a specified number of forward looking days (**Days**) or a given quantity (**Quantity**). For more information, see "Time-phased safety days" on page 1407. • **TimePhasedSafetyDaysTotal**—safety stock levels are calculated daily. Based on effective values in the **TimePhasedSafety** table, safety stock is set to the sum of demand collected over some number of forward looking days (**Days**) and a given quantity (**Quantity**). For more information, see "Time-phased safety days" on page 1407. **Default value:** FixedQuantity **Note:** This field was modified in Version 2016.2. **Note: TimePhasedRangeOfCoverage** does not calculate dynamic safety stock for the last period of demand if there is no future demand.		

Table 7.49: SafetyStockPolicy (Mfg) fields

Field name	Description	Data type	Key
	Note: For all dynamic rules, (that is, those other than **FixedQuantity** and the **TimePhasedQuantity*** settings, specific types of demands can be included or excluded from use in determining calculated safety stock levels based on the **DemandType.SafetyStockDemandUsage** setting.		

Table 7.49: SafetyStockPolicy (Mfg) fields

Field name	Description	Data type	Key
SafetyStockRule	Specifies how safety stock levels are maintained for parts using this policy. In other words, once the safety stock levels are known, under what conditions will orders to replenish safety stock be generated. Valid values are: • **Always**—always maintain the safety stock level as calculated based on the setting in **SafetyStockQuantityRule**. If an order is required to bring inventory to that level, then generate a planned order or expedite an existing order as early as allowed based on order rescheduling rules (**Type.ProcessingRule** / **Status.RescheduleRule**), order generation rules (**PartSource.OrderPolicy.OrderGenerationRule**) and the **Part.SafetyStockDate** rule. • **Ignore**—safety stock is never maintained regardless of the settings in other fields. • **IfDemand**—orders for bringing inventory to the safety level will be generated only if there is a non-ignored demand record for the part (**Order.Type.ProcessingRule** does not equal 'Ignore', and **Status.ProcessingRule** does not equal 'Ignore' or quantity is not equal to 0). This includes dependent and independent demand. • **IfActivity**—if there are non-ignored ScheduledReceipts (**Status.IgnoreSupply** does not equal 'Y' or the **Quantity** does not equal 0) or non-ignored IndependentDemands (**Order.Type.ProcessingRule** does not equal 'Ignore', **Status.ProcessingRule** does not equal 'Ignore', or **Quantity** is not equal to 0) or dependent demands. • **OrderPointAverage**—orders are generated when inventory levels fall below the order point threshold as determined by the setting in the **SafetyStockQuantityRule** field. The order quantity is determined by the value in **Part.AverageQty** (or **Part.SafetyStockQty** if **Part.AverageQty** is less than or equal to 0), and orders of this size are generated until inventory levels meet or exceed the calculated order point threshold. The start date of the generated planned orders matches the DueDate of the demand they are satisfying. • **OrderPointOver**—orders are generated when inventory levels fall below the order point threshold as determined by the setting in the **SafetyStockQuantityRule** field. Order quantities are set to the largest number that will bring inventory levels closest to the maximum of either the order point threshold or **Part.AverageQty** without exceeding it. If using this setting, it is recommended to have the **SafetyStockQuantityRule** field set to "FixedQuantity", and ensure **Part.AverageQty** is set to a value greater than **Part.SafetyStockQty**. RapidResponse will then plan orders	String (Enum)	

Table 7.49: SafetyStockPolicy (Mfg) fields

Field name	Description	Data type	Key
	using these two fields as an upper and lower bound, respectively. • **OrderPointUnder**—orders are generated when inventory levels fall below the order point threshold as determined by the setting in the **SafetyStockQuantityRule** field. Order quantities are set to the smallest number that will bring inventory levels equal to or greater than the maximum of either the order point threshold or **Part.AverageQty**. This setting is intended to keep inventory levels above the order point threshold. The start date of the generated planned orders will match the DueDate of the demand they are satisfying. • **Soft**—safety stock is an available buffer. **ReschedDate** and **RecommendedDate** are left as **DueDate** if existing supplies retain inventory >=0 rather than >= SafetyStock. **Default**: Always		
Value	A unique string identifier for this safety stock policy.	String	Yes
Parts	Set of Part records that reference this safety stock policy.	Set	

ScenarioSetting table

The **ScenarioSetting** table is used to specify the currency conversion date to use for converting calculated Money fields. This is typically specified as part of a scenario perspective, and is intended to be used to compare Money values calculated using conversion rates from different periods.

This table can contain only one record, and its value is specified by a perspective definition.

Table 7.50: ScenarioSetting (Core) fields

Field name	Description	Data type	Key
CurrencyAsOfDate	The historical currency as of date that contains the conversion rates to use for converting calculated Money fields. This value is used only if the value specified is earlier than the date used to determine when historical or actual rates are used to convert a value.	Date	

ShipmentPolicy table

The **ShipmentPolicy** table is used to indicate whether associated independent demands are eligible to be broken into partial shipments.

Table 7.51: ShipmentPolicy (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this ShipmentPolicy record. **Referenced table:** ControlSet	Reference	Yes
Description	A description of this shipment policy.	String	
PartialRule	Controls whether independent demands using this shipment policy are eligible to be split into partial shipments. Any independent demands that belong to a ship set cannot be split into partial shipments regardless of the setting on this field (for more information, see "ShipSet table" on page 592). Valid values are: • **Complete**—The entire independent demand quantity must be shipped as a whole. If using non-blocking allocations, component supply allocations are synchronized to the planned available date for the demand (determined by the gating component, if any). This allows any earlier component supplies associated with a late demand to be re-directed towards other demands that might otherwise be late. • **Partial**—The independent demand quantity can be split into partial shipments. If using non-blocking allocations, component supply allocations are synchronized to the due date for the demand. This allows earlier component supplies associated with the amount of a demand that will be late to be re-directed towards other demands that might otherwise be late. **Default value:** Partial Note: For more information about non-blocking allocations, see "Multi-level search logic" on page 1863.	String (Enum)	
Value	A unique identifier for this shipment policy. This field is referenced by the **ShipmentPolicy** field on the **IndependentDemand** table.	String	Yes
Independent Demands	Set of **IndependentDemand** records that reference this ShipmentPolicy value.	Set	

ShipSetType table

The **ShipSetType** table is used to enable or disable non-blocking allocations across the independent demands within a given ship set.

When non-blocking allocations are enabled at the part level, the allocation of a component's supply to a demand can be synchronized with the latest allocated supply from any of its sibling components in order to free up earlier supplies that can be used to potentially satisfy different demands that might otherwise have been late. If non-blocking allocations are further enabled at the ship set level, then

allocations of supply to the demands that belong to that ship set can be synchronized with the latest allocation of supply within that ship set (typically, the most gating). This can free up earlier supplies to satisfy other demands outside of the ship set (for example, demands belonging to another ship set or not associated with any ship set).

Table 7.52: ShipSetType (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set this record belongs to. **Referenced table:** ControlSet	Reference	Yes
Description	A description of this ship set type.	String	
MultiLevelSearchRule	Specifies whether non-blocking allocations are used within ship sets of this type. Valid values are: • **Ignore**—non-blocking allocations are disabled for demands in ship sets that reference this type. • **Use**—non-blocking allocations are enabled for demands in ship sets that reference this type. As necessary, component supply allocations are synchronized with the latest available supply that will be allotted to any demands in the ship set. This can potentially free up earlier component supplies to satisfy other demands or ship sets which might otherwise be late. Note that in order for this setting to take effect, non-blocking allocations must also be enabled at the part type level for the affected parts (that is, their **Part.MultiLevelSearchRule** value should be set to "Use"). **Default value:** Ignore	String (Enum)	
Value	A unique identifier for this ship set type.	String	Yes
ShipSets	Set of **ShipSet** records that reference this value.	Set	

SHSCConfiguration table

The **SHSCConfiguration** table contains control settings used by the Self-Healing Supply Chain.

This table was added in Version 2016.2, Service Update 25.

Table 7.53: SHSCConfiguration (Solutions) fields

Field name	Description	Data type	Key
CommitToParentScenario	Determines whether changes in the Self-Healing Working Plan scenario are committed to the parent scenario of Self-Healing Current Plan (Yes) or not (No). The Self-Healing Current Plan and the Approved Actions scenarios are hard-coded into the Commit Lead Time Corrections form. If the parent scenario for Self-Healing Current Plan is set to a different scenario than Approved Actions, then the Approved Actions scenario should be changed to the parent scenario that is used instead. Similarly, if the parent scenario for Self-Healing Current Plan is set to a different scenario than Approved Actions, then the scenario in the Auto Heal Lead Times - Approved Actions scheduled task that is part of the Self-Healing Lead Time automation chain should also be changed to point to the parent scenario that is used instead. Default: Yes	Boolean	
FutureYieldHorizon	Determines how many future periods of yield forecast results are sent from the Machine Learning service. Default: 26	Integer	
FutureYieldCalendar	Determines what calendar periods to use to define the yield forecast result from the Machine Learning service. Default: Weeks **Referenced table:**Calendar	Reference	
HistoricalHorizon	Determines how many historical periods to include in lead time analysis. For example, how many months of historical data will be included. Default: 24	Integer	
HistoricalYieldHorizon	Determines how many historical periods to include in yield analysis. For example, how many weeks of historical data will be included. Default: 156		
HorizonCalendar	Determines what calendar periods to use to define the lead time history. For example, months or weeks. Default: Months **Referenced table:**Calendar	Reference	

Table 7.53: SHSCConfiguration (Solutions) fields

Field name	Description	Data type	Key
LeadTimeType	When running the Machine Learning service for the first time, the Automated Lead Time Type value set here will be used for all ItemSource records. Default: Auto **Note:** After the first run of the Machine Learning service, you can change the AutomatedLeadTimeType from the default value and assign different AutomatedLeadTimeType records to ItemSource records. To change the AutomatedLeadTimeType for an ItemSource, use the Item Source worksheet in the Self-Healing Data workbook. **Note:** The AutomatedLeadTimeType record should be created first in the Automated Lead Time Type worksheet of the Control Tables workbook. **Referenced table:**AutomatedLeadTimeType	Reference	
YieldType	When running the Machine Learning service for the first time, the Automated Yield Type value set here will be used for all ItemSource records. Default: Null **Note:** After the first run of the Machine Learning service, you can change the AutomatedYieldType from the default value and assign different AutomatedYieldType records to ItemSource records. To change the AutomatedYieldType for an ItemSource, use the Item Source worksheet in the Self-Healing Data workbook. **Note:** The AutomatedYieldType record should be created first in the Automated Yield Type worksheet of the Control Tables workbook. **Referenced table:**AutomatedYieldType	Reference	
NewSupplyStatus	Displays the default OrderStatus to use for disabling ScheduledReceipt records for the Self-Healing Supply Chain. This variable should point to a record where **SupplyStatus.IgnoreSupply** = 'Y'. Default: Ignore **Referenced table:**SupplyStatus	Reference	

Table 7.53: SHSCConfiguration (Solutions) fields

Field name	Description	Data type	Key
OrderPolicy	Displays the default Order Policy to use for disabling PartSource records for the Self-Healing Supply Chain. This field should point to a record where **OrderPolicy.OrderGenerationRule** = 'NoOrders', **UseFixedLeadTime** = 'Y', **OrderPolicy.YieldUsage** ≠ 'Ignore', and **OrderPolicy.YieldUsage** ≠ 'ScrapPiece'. **Referenced table:**OrderPolicy	Reference	

SOPAnalyticsConfiguration table

The **SOPAnalyticsConfiguration** table is a control table used to define default parameters for forecasts and disaggregation rate calculations. It holds only one record which is populated using the **SOP Analytics Configuration** worksheet in the Control Tables workbook. This record can be modified on a scenario-by-scenario basis, allowing you to use this table to model various statistical forecast and disaggregation scenarios.

Note that many of the disaggregation parameters in this table can be overridden for a particular part-customer and forecast category combination by providing values in the **ForecastDisaggregationParameters** table, or they can be overridden for all part-customers associated with a given forecast category by providing values in the **ForecastDisaggregationParametersByCategory** table.

Table 7.54: SOPAnalyticsConfiguration (Mfg) fields

Field name	Description	Data type	Key
CalcForecastEnd Date	The calculated date on which to stop reporting disaggregation rates (exclusive). If a positive value is provided in **ForecastEndOffset**, then this is calculated as **CalcForecastStartDate** plus(offset by) that number of **CycleCalendar** intervals. Otherwise, this is calculated as **CalcForecastStartDate** plus one **CycleCalendar** interval.	Date	
CalcForecastStart Date	The calculated date on which to start reporting disaggregation rates (inclusive). If a positive value is provided in **ForecastStartOffset** , then this is calculated as **CalcHistoricalEndDate** plus(offset by) that number of **CycleCalendar** intervals. Otherwise, this is the same as **CalcHistoricalEndDate**.	Date	

Table 7.54: SOPAnalyticsConfiguration (Mfg) fields

Field name	Description	Data type	Key
CalcHistoricalEnd Date	The calculated last date on which historical data can be collected (exclusive). For example, this defines the date back from which historical data can be collected for use in determining disaggregation rates. Set to the nearest **CycleCalendar** interval on or before RunDate (for example, the beginning of the current month).	Date	
CycleCalendar	The calendar that reflects the S&OP cycle used to calculate the historical end date, the forecast start date, and the forecast end date. Also used to define holdout region and forecast lag associated with best fit calculations. This is typically a monthly calendar. **Referenced table:** Calendar	Reference	
Disaggregation ActualsCategory	The historical demand category used to calculate disaggregation rates. **Referenced table:** HistoricalDemandCategory	Reference	
Disaggregation Calendar	The disaggregation calendar is the one and only spreading interval used for all disaggregation. It defines the periods that orders can be disaggregated into, so forecast details are entered and stored at the disaggregation calendar level. It should be the smallest bucket needed for working with forecast quantities. Typical values include week and month. Note that this value can be overridden at the part customer level by providing a valid reference in the **PartCustomer.DisaggregationCalendar** field. Otherwise, if that reference is left Null for a given part customer, the value provided in this field is used. **Referenced table:** Calendar	Reference	
Disaggregation HistoricalInterval Count	The number of inner calendar periods before the forecast start date that are used to collect historical data and causal factors used to calculate disaggregation rates.	Integer	
Disaggregation InnerCalendar	The inner calendar is used in forecast disaggregation with seasonal trends to define the length of a season. This calendar is divided by the outer calendar to provide the index used to determine which period a forecast is disaggregated into. For example, with season month-in-year disaggregation, this would be set to a monthly calendar. Months with higher values in them would then receive more of the data being disaggregated. If forecast disaggregation is not seasonal, this should be set to the same value as the outer calendar. **Referenced table:** Calendar	Reference	

Table 7.54: SOPAnalyticsConfiguration (Mfg) fields

Field name	Description	Data type	Key
Disaggregation OuterCalendar	The outer disaggregation calendar is used to define the period over which a forecast is disaggregated. For example, with season month-in-year disaggregation, this would be set to a yearly calendar. The calendar referenced by this field cannot represent smaller intervals than the one referenced by the inner calendar (they can reference the same calendar if disaggregation is not seasonal). The outer calendar marker should also always land directly on the inner calendar marker. For example, with month-in-year disaggregation, the yearly (outer) calendar marker should land on a marker that defines the start of a monthly (inner) calendar. **Referenced table:** Calendar	Reference	
Forecast Disaggregation OverrideCategory	Supports default disaggregation override rates by forecast category. Override rates are used in place of the calculated disaggregation rates (either the default disaggregation rates or those for a particular part-customer and category). **Referenced table:** HistoricalDemandCategory	Reference	
ForecastEndOffset	Offset from the calculated forecast start date to stop reporting disaggregation rates (expressed in **CycleCalendar** intervals). For example, if using a monthly Cycle calendar, then a value of "24" indicates to report disaggregation rates for 24 months.	Integer	
ForecastStartOffset	Offset from the calculated historical end date to start reporting disaggregation rates (expressed in **CycleCalendar** intervals). For example if using a monthly Cycle calendar, then a value of "0" indicates to start reporting disaggregation rates at the beginning of the current month. This value also impacts the calculation of rolling weight horizons in consensus demand plan calculations. For information, see HistoricalDemandHeaderRollingWeight. **NOTE**: A negative value is treated the same as zero (0).	Integer	
RunDate	The current system date, used to calculate the historical end date, forecast start date, and forecast end date. **Referenced table:** Calendar	Reference	
RServerAvailable	Indicates whether the R Server is available. This is the server supporting the R programming language that gives access to some advanced forecasting functions and methods of outlier detection that are not otherwise supported in RapidResponse. Support for R is only available with the OnDemand RapidResponse Service, and if the optional R forecast capability has been configured.	Boolean	

SourceRule table

The **SourceRule** table determines how PartSource values are interpreted when a part has more than one active part source that is eligible to satisfy a given requirement. For example, this table can be used to determine how target percentage splits between suppliers are interpreted and thus used to determine the amount of the planned requirements sourced from each. This table is referenced from the **Part** table (**Part.SourceRule** field references this table).

Table 7.55: SourceRule (Mfg) fields

Field name	Description	Data type	Key
AllotmentRule	Specifies how a planned requirement is sourced when there are multiple eligible part sources with the same priority. That is, when there are one or more eligible **PartSource** records with the same **Priority** value, this setting indicates how their **Target** values are used in determining the sourcing of the requirements. Valid values are: • **Ongoing**—each planned requirement is fully allocated to the eligible part source that will be the furthest away from (and under) its ongoing target if not used to source that supply. The ongoing target for each **PartSource** record is determined by first dividing its **Target** field by the sum of the **Target** fields from all active **PartSource** records for a given **Priority.** The resulting value is then multiplied by the total quantity of supply allocated across all eligible part sources so far including the current requirement being sourced. These ongoing target values are then compared against the total supply allocated to each part source to determine which should supply the requirement. • **OngoingToDate**—each planned requirement is fully allocated to the eligible part source that has the lowest calculated quota rating based on all previously sourced supply. This option is similar to "OnGoing" but uses slightly different logic which does not include consideration for the quantity of the current requirement being sourced. The quota rating for each PartSource record is determined by dividing its Target field by the sum of the Target fields from all active PartSource records for a given Priority (this yields a target ratio). The total quantity allocated across all eligible part sources, up to but not including the current requirement, is then divided by the calculated target ratio to give the quota rating (with the lowest used to source the requirement). If multiple PartSource records have the same quota rating, the higher Target value is chosen, and if those are the same then the one with the lower SecondaryPriority value is (by default) chosen. • **Proportional**—each planned requirement is split between eligible part sources based on their proportional target values. The proportional target for each **PartSource** record is determined by dividing its **Target** field by the sum of the **Target** fields across all active **PartSource** records of a given **Priority** level. The proportional targets are then multiplied by the quantity of the current requirement to determine the amount to be provided by each source. If order multiples or minimums are applicable, then these are applied separately after the demand has been	String (Enum)	

Table 7.55: SourceRule (Mfg) fields

Field name	Description	Data type	Key
	split between all eligible part sources and can result in excess supply (for these cases, consider using "ProportionalLotSize"). • **ProportionalLotSize**—each planned requirement is split between eligible part sources based on their proportional target values. Proportional targets are recalculated after each portion of the supply is sourced and the outstanding requirement to be sourced adjusted for any lot-sized quantities. With this setting, the **PartSource** record with the largest **Target** is selected first, and its proportional target determined by dividing its **Target** value by the sum of the **Target** values across all active **PartSource** records of a given **Priority** level. The proportional target is then multiplied by the quantity of the requirement to determine the amount to be provided by the source. A supply is then planned for this initial amount and any lot-sizing applied at this time. The **PartSource** with the next largest **Target** is then selected, and its proportional target calculated based on the **Target** values across all eligible **PartSource** records that haven't yet been used for the current requirement. The proportional target is then multiplied by the remaining requirement quantity after adjusting for the previously sourced portions including any lot-sizing. This process repeats until the entire requirement has been sourced. If during the sourcing process multiple eligible **PartSource** records have the same **Target**, then the one with the lowest **SecondaryPriority** is (by default) chosen. Also, although use of this setting can help reduce excess from lot-sizing, the percentage supply splits will not necessarily reflect the specified **Target** values and in some cases eligible part sources might not be used at all (if there is enough excess from other supplies). **Default value:** Ongoing **Note:** If needed an initial allotment value can be specified in **PartSource.ToDateQty** to reflect any prior sourcing decisions not reflected in RapidResponse. This value is then always included in the calculations for the "Ongoing" and "OngoingToDate" options. **Note:** If using multi-level search logic for part source selection, the "OngoingToDate" and "ProportionalLotSize" options are not supported ("Ongoing" and "Proportional" logic respectively will be used instead). **Note:** This field was modified in Version 2016.2, Service Update 6. For more information about use of the settings in this field, see "Part source selection" on page 1377.		

Table 7.55: SourceRule (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this SourceRule record. **Referenced table:** ControlSet	Reference	Yes
DateEffectivityRule	When new supply is needed to satisfy a demand, this setting controls how sourcing is handled in cases where the demand date, less any safety lead time defined at the part level, falls outside of the effective window for all potential part sources. If this adjusted demand date does not fall between **FirstEffectiveDate** and **LastEffectiveDate** on any **PartSource** record, then the requirement will either be shifted into an effective period or left unsatisfied. Valid values are: • **AdjustedDemandDate**—If the adjusted demand date falls outside the effective date range for all part sources, then supply will not be planned for the demand which will be left unsatisfied. Any demands that go unsatisfied due to part source effectivity are logged in the **DemandException** table with a **Type** value of "SourceEffectivityWindow". • **Normal**—If the adjusted demand date falls outside the effective date range for all part sources, then supply can still be planned for the demand. Planned supply due dates must still be within the part source's effective window which will necessarily make them earlier or later than the demand date. However if **SupplyStatus.AllowLatePlan** is set to "Y", then in some cases planned supply due dates might be set beyond the part source's effectivity range. **Default value:** Normal **Note:** This field was added in Version 2016.2, Service Update 8.	String (Enum)	
Description	Additional information about this SourceRule record.	String	
PriorityRule	When sourcing planned requirements by priority, specifies how values in the **PartSource.Priority** and **PartSource.SecondaryPriority** fields are interpreted. Valid values are: • **Ascending**—lower numerical values equate to higher priorities (for example, part sources with lower **Priority** values will be used first when possible). • **Descending**—higher numerical values equate to higher priorities (for example, part sources with higher Priority values will be used first when possible). **Default value:** Ascending	String (Enum)

SpreadProfile table

The **SpreadProfile** table defines a spreading profile used for forecast purposes. This table is referenced from **DemandType** table. For information about a spread profile, see "Forecast spreading" on page 1426.

You can define the characteristics of a spread profile. For example, to define a flat profile that spreads the forecast evenly over each SecondCalendar interval, define a SpreadProfile with **NumberOfPoints** equal to zero or one.

Table 7.56: SpreadProfile (Mfg) fields

Field name	Description	Data Type	Key
ControlSet	The control set associated with this SpreadProfile record. **Referenced table:** ControlSet	Reference	Yes
Description	The description of the demand spread profile.	String

SubstituteGroupType table

The **SubstituteGroupType** table is referenced by the **SubstituteGroup** table. It defines the processing rules that are associated with groups of substitutable components within a given assembly.

Table 7.58: SubstituteGroupType (Mfg) fields

Field name	Description	Data type	Key
ComponentRule	When using on hand or scheduled receipts to satisfy demand for a substitutable component, this field determines how different components from the group can be mixed together on a single assembly order. Valid values are: • **AssemblyUnit**—only one substitutable component can be used for each unit of assembly supply in the order. That is, component supply can only be used in increments equal to the component's QuantityPer value. • **Single**—only one substitutable component can be used for each assembly supply order. If planned orders are required to fully satisfy a demand, they are created on that same component. However, if the demand is only being satisfied by planned orders, then planned order creation is determined by the BillOfMaterial.Target field. • **Unrestricted**—no restrictions on how substitutable components can be mixed together on a supply order for the assembly. If planned orders are required to fully satisfy the demand, they created across the group's components in the ratio determined by the BillOfMaterial.Target field. **Default value**: Single	String (Enum)	
Component SourceRule	When planned orders are required to satisfy dependent demands placed on substitutable components, this setting determines how the requirements are split between those components. Valid values are: • **Ongoing**—each dependent requirement from the assembly is assigned to the one substitutable component in the group that will be furthest away from its ongoing target if not used to satisfy the demand. • **Proportional**—each dependent requirement from the assembly is split proportionally between substitutable components in the group based on their weighted targets as calculated from **BillOfMaterial.Target**. **Default value:** Proportional **Note:** For more information about this field's usage, see "Define planned order generation" on page 1571.	String (Enum)	

Table 7.58: SubstituteGroupType (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this SubstituteGroupType record. **Referenced table:** ControlSet	Reference	Yes
Description	A description of this SubstituteGroupType record.	String	
ProcessingRule	Controls whether component substitution is enabled for groups of this type. Valid values are: • **Ignore**—component substitution is disabled within the group. Demand on the primary component in the group can only be satisfied by its own supply. • **OptionRatio**—component substitution is disabled within the group. This type is used to group related option ratio components under an assembly. It allows incremental availability to be rolled up on each component within the group, and one unit of supply of the parent can therefore be built when any of the option components are available (otherwise, supply is required of each option component before a unit of the assembly can be built). • **Substitute**—component substitution is enabled within the group. Substitute components can be used to satisfy demand on the primary component in the group. **Default value**: Ignore	String (Enum)	
SubstituteGroups	Set of **SubstituteGroup** records that reference this SubstituteGroupType value.	Set	
SupplyPreference	When acceptable supply is available on multiple components in the group, this settings controls which of those components has its current supply used first. Valid values are: • **Earliest**—preference is given to the component with the earliest available supply that can be used. With this setting, onhand supplies are consumed first, and then the earliest scheduled supplies. Note that in cases where multiple components have supply available on the same date, then the one with the lowest value in the **BillOfMaterial.SubstitutionSequence** field is used first. • **Sequence**—preference is given to the component with the lowest value in the **BillOfMaterial.SubstitutionSequence** field. **Default value**: Sequence	String (Enum)	
Value	A unique identifier for this type of substitute group. This value is referenced by each record in the **SubstituteGroup** table that belongs to this group type.	String	Yes

SupplyAllocationType table

The **SupplyAllocationType** table is referenced by the **SupplyAllocation** table, and is used to determine if a manual supply allocation should be processed by RapidResponse analytics.

Table 7.59: SupplyAllocationType (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this SupplyAllocationType record. **Referenced table:** ControlSet	Reference	Yes
Description	A description of this SupplyAllocationType record.	String	
ProcessingRule	Controls whether the manual supply allocation record is processed by RapidResponse. Valid values are: • **Ignore**—The supply allocation is ignored. • **Use**—The supply allocation is processed. **Default value**: Use	String (Enum)	
PTFLastDueRule	Specifies whether supply allocations of this type are considered in planning time fence logic for part sources having an **OrderPolicy.PTFRule** setting of either "LastDueFence", "LastDueLead", "LastDueFenceAll" or "LastDueLeadAll". Valid values are: • **Include**—Supplies of this type are included in the **PTFDate** calculation for part sources that use any of the "LastDue" planning time fence rules. This means the due date on the last supply allocation associated with an order of this type for the part can potentially be set as the part source's **PTFDate** (assuming it is beyond the part source's fence or lead time value and later than any other scheduled supply from the part source). • **Exclude**—Supplies of this type are excluded from the **PTFDate** calculation for part sources that use any of the "LastDue" planning time fence rules. This means the due date on the last supply allocation associated with a supply of this type for the part will never be set as the part source's **PTFDate** (even if it is beyond the part source's fence or lead time value and later than any other scheduled supply from the part source). **Default value**: Include **Note:** This field was added in Service Update 1908 (prior to this, it was not possible to exclude specific supply allocation types from the **PTFDate** calculation). For more information, see "Determining the PTFDate" on page 1344	String (Enum)	

Table 7.59: SupplyAllocationType (Mfg) fields

Field name	Description	Data type	Key
Supply Allocations	Set of SupplyAllocation records that reference this SupplyAllocationType value.	Set	
Value	A unique identifier for this SupplyAllocationType record. This field is referenced by the **Type** field on the **SupplyAllocation** table to determine the processing policies for a particular manual supply allocation.	String	Yes

SupplyStatus table

The **SupplyStatus** table controls the state of supplies (unreleased work orders, work orders, released work orders, planned purchase orders, and firm purchase orders). This table is referenced from the **PartSourceType** and **ScheduledReceipt** tables.

Table 7.60: SupplyStatus (Mfg) fields

Field name	Description	Data type	Key
AllowLatePlan	This setting controls whether a supply's due date is allowed to be set later than its associated demand date and applies only when using constraints and/or multi-level search logic. When using constraints, this setting determines whether a supply's due date can be set later than would be needed to meet the demand date in cases where there is insufficient capacity available to meet that demand date. When using multi-level search, this setting controls whethers a supply's due date can be set later than neethe demand date in cases where there is insufficient capacity or availaiblity of component materials. This allows supplies to be scheduled when they are expected to have capacity, rather than to their (earlier) demand dates. This setting affects planned orders, as well as scheduled receipts that are reschedulable. Valid values are: • **Y**—If using constraints, supplies are planned for when they are expected to have capacity. If using multi-level search, supplies are planned for when they are expected to have both capacity and material availability. • **N**—Supplies are always planned to meet demand dates (This is the recommended value.) **Default value**: N For more information about AllowLatePlan, see "AllowLatePlan" on page 1663.	String (Enum)	

Table 7.60: SupplyStatus (Mfg) fields

Field name	Description	Data type	Key
AvailableDate Limit	A supply order's **AvailableDate** is always limited by constraint and material availability, as well as the absolute available date limit as discussed in "AvailableDateLimit" on page 1666. Subject to these limitations, this field determines the earliest date that RapidResponse can set the available date for supply orders. Valid values are: • **CalcRequestStart—**build the supply based on its **CalcRequestStartDate.** Supply cannot be available earlier than **CalcRequestStartDate** + lead time, and constraint cannot be allocated any earlier than **CalcRequestStartDate** converted to a constraint date. Note that each supplies **CalcRequestStartDate** is derived from the original **RequestDate** provided on the (earliest) driving independent demand it satisfies, and which is then propagated down the product structure and adjusted for lead time at each component level. Therefore, this option is intended for use with supplies satisfying independent demands that are configured for two-date planning (have their **OrderPriority.TwoDatePlanningRule** set to "Use"). If this option is used with supplies having an undefined **CalcRequestStartDate**, then it is equivalent to using the "CalcStart" option (for example, this can occur with supplies satisfying consensus forecast demand or supplies satisfying independent demands with an undefined **RequestDate**). Additionally, if the calculated start date is earlier than the date determined from this setting, then it becomes the available date limit instead ("CalcStart" setting is used). • **CalcStart**—build the supply based on its calculated start date (**CalcStartDate** for scheduled receipts and **StartDate** for planned orders). Supply cannot be available earlier than **CalcStartDate/StartDate** + lead time , and constraint cannot be allocated any earlier than **CalcStartDate/StartDate** converted to a constraint date. • **Due**—build the supply so that the earliest it can be completed is the order's due date (even if rescheduled earlier). In addition, constraint cannot be allocated before **EffStartDate** (**StartDate** for planned orders) converted to a constraint date. • **Now**—if a supply order is unconstrained, it can be built as soon as materials are available (subject to the absolute limits on available date . If all material is available before the FirstEffectiveDate on the BillOfMaterial record through which the demand	String (Enum)	

Table 7.60: SupplyStatus (Mfg) fields

Field name	Description	Data type	Key
	exploded, the available date on the supply is still reported based on material date and might end up being seen as available before the beginning of the associated BOM effectivity range. If a supply order is constrained and there is sufficient constraint to complete the order on time, then it will not start consuming constraint until its calculated start date (even if materials are available before that date). If a supply order is constrained and there is insufficient constraint to complete the order on time, then it can start consuming constraint as needed to meet the supply's rescheduled date (subject to the absolute limits on available date). **Default value**: CalcStart **Note:** For more information about how this field affects Constraint Analysis calculations, see "AvailableDateLimit" on page 1666. For more information about how this field affects incremental availability calculations, see "Defining when order splits can occur" on page 1480. **Note:** When push-planning logic (distribution planing) is used, some pushed supplies might up with available dates that are later than the limit determined by the AvailableDateLimit setting.		
CoByProduct Usage	Used with scheduled receipts for parts that are defined as the primary product in a co-product or by-product relationship. This field indicates whether co-product and by-product supply should be generated from the scheduled receipt. Valid values are: • **Generate**— Co-product and by-product supply is automatically generated from the primary product's scheduled receipt based on the values defined on the associated BillOfMaterial records. This setting is used for scheduled receipts for which the expected co-product or by-product supply has not been generated. • **DoNotGenerate**— Co-product and by-product supply is not generated from the scheduled receipt. This setting is used for scheduled receipts in the later stages of the production process where any co-product or by-product supplies have already been created and are being managed separately from the primary product. For more information, see "Co-products and by-products" on page 1581. **Default value**: Generate **Note:** If the **State** field is set to "Historical", then co-product and by-product supplies are not generated on the scheduled receipt regardless of the setting in this field.	String (Enum)	

Table 7.60: SupplyStatus (Mfg) fields

Field name	Description	Data type	Key
ConstraintRule	Processing rule that affects how constraint is applied to scheduled receipts when calculating AvailableDate. This field makes it possible to prevent available date changes to scheduled receipts, even if total load exceeds the available constraint. For example, this may be used when a scheduled receipt represents a firm commitment that has been agreed to by an external supplier. Valid values are: • **Consume**—consume constraint, but do not consider its availability when calculating AvailableDate. This setting is intended for use with supplies that represent a firm commitment (for example, supplies that have been scheduled by an external system). • **BeforeAD**—consume Constraint and use its availability when calculating AvailableDate. This is the recommended setting. **Default:** Consume **Note:** This field is now obsolete and maintained only for backwards compatibility. It is recommended that you always set this field to **BeforeAD**. If you require the behavior provided by **Consume**, set the **RescheduleRule** field to **Scheduled.**	String (Enum)	
ControlSet	The control set associated with this SupplyStatus record. **Referenced table:** ControlSet	Reference	Yes
Description	A description of this type of SupplyStatus. **Default value**: blank string	String	
ExpediteLimit	Specifies the range that supplies can be expedited. Valid values are: • **Past**—date will be set to whatever date the supply is needed, including the past, if necessary. • **PTFDate**—supplies can only be expedited up to the calculated **PartSource.PTFDate**. Note that this option ignores the **OrderPolicy.LotSizeLastOrder** setting. For more information about the **PTFDate** calculation, see "Determining the PTFDate" on page 1344 • **RunDate**—supplies can only be expedited up to the Part.PlanningCalendars.RunDate. FirstDate. • **DueDate**—supplies can't be expedited. The only allowed recommended date changes are cancels and delay. **Default value:** Past	String (Enum)	

Table 7.60: SupplyStatus (Mfg) fields

Field name	Description	Data type	Key
IgnoreStartDate	Specifies when rescheduling a supply's DueDate whether to always update the Supply StartDate and associated dependent demand Allocation DueDate. Valid values are: • **Y**—RapidResponse ignores the **ScheduledReceipt.StartDate** and **Allocation.DueDates.** Instead, **ScheduledReceipt.CalcStartDate** is used (calculated using the ScheduledReceipt.ReschedDate) to offset by the applicable lead-time fields. **SupplyType.ProcessingRule** and **SupplyStatus.RescheduleRule** are also taken into consideration for their effect on the **ScheduledReceipt.ReschedDate**. • **N**—RapidResponse uses the S**cheduledReceipt.StartDate** and **Allocation.DueDates**. **Default value:** N	Boolean	
IgnoreSupply	Specifies whether any type of supply should not be considered in netting and explosion. Valid values are: • **Y**—RapidResponse ignores all scheduled receipts associated with this SupplyStatus. • **N**—RapidResponse considers all scheduled receipts associated with this SupplyStatus. **Default value**: N	Boolean	
IncrementalSplit	For parts that have incremental availability calculations turned on, this field allows the calculations to be turned off on a supply-by-supply basis. Valid values are: • **FromPart**—Incremental availability calculations are performed for this supply if they have been turned on for the part (as set by the **Part.IncrementalRule** field). Otherwise, incremental availability calculations are not performed for the supply. • **Off**—Incremental availability calculations are not performed for this supply (regardless of the setting on the Part.IncrementalRule field). **Default value**: FromPart	String (Enum)	

Table 7.60: SupplyStatus (Mfg) fields

Field name	Description	Data type	Key
LeadTime Override	Specifies whether lead time calculations use values defined on the part source, or are overridden with values defined on the scheduled receipt. This setting allows lead time overrides to be defined on a scheduled receipt by scheduled receipt basis. Valid values are: • **Yes**—Lead time values from the scheduled receipt are used in lead time calculations. • **No**—Lead time values from the part source associated with the scheduled receipt are used in lead time calculations. • **FromOrder**—The control setting on the supply order (**SupplyType.LeadTimeRule**) is used to determine whether lead time values from the scheduled receipt or part source are used in lead time calculations. **Default value**: No For more information on overriding lead time on scheduled receipts, see "Lead time overrides from scheduled receipts" on page 1328.	String (Enum)	
ModelUsage	Indicates how the model associated with a given scheduled receipt is determined. The value reported in the calculated **ScheduledReceipt.Model** field is also affected by this setting. Actual usage of the model in analytic calculations is then set by the part's **MUEPoolNettingType.ModelRule** value. Valid values are: • **Ignore**—model is set to the default model. This is the first value loaded in the **Model** table and typically has a value of "None". The input value provided in **ScheduledReceipt.InputModel** is ignored. • **Normal**—model is set to the input value provided in **ScheduledReceipt.InputModel**. **Default value:** Normal	String (Enum)	
PartialExplode	Specifies whether supply assigned this status only generates dependent demand when **BillOfMaterial.OperationNumber** is greater than or equal to **ScheduledReceipt.CurrentOperation** before generating dependent requirements (allocations). Valid values are: • **Y**—yes • **N**—supply assigned this status does not perform this test when calculating explosion. **Default value**: N	Boolean	

Table 7.60: SupplyStatus (Mfg) fields

Field name	Description	Data type	Key
PrioritySource	Controls how the priority on scheduled receipts and planned orders is set. For scheduled receipts, this setting controls how a scheduled receipt's effective order priority (**ScheduledReceipt.EffOrderPriority**) is determined. For planned orders from a given part source, this setting determines how a planned order's priority (**PlannedOrder.OrderPriority**) is determined. Valid values are: • **Average**— effective order priority is set to an average of the priorities associated with all demands satisfied by the supply. That is, the **OrderPriority.PlanningPriority** values found on all demands satisfied by the supply are summed together and then divided by the total number of demands; the **OrderPriority.Value** associated with the closest **PlanningPriority** value that is equal to or lower than that calculated average is then reported. • **FromInput**— The use of this value in setting priority depends on whether the supply is a scheduled receipt or a planned order. For scheduled receipts, the effective order priority is taken from the input **OrderPriority** value on the **ScheduledReceipt** record. For planned orders, the order priority is set to the input **OrderPriority** value on the triggering **IndependentDemand** record that led to the creation of this supply. • **Highest**— effective order priority is set to the highest priority associated with any demand satisfied by the supply during netting calculations. That is, the **OrderPriority.Value** associated with the lowest **OrderPriority.PlanningPriority** number on any demand satisfied by the supply is reported. • **WeightedAverage**— effective order priority is set to a weighted average of the priorities associated with all demands satisfied by the supply during netting calculations. That is, the **OrderPriority.PlanningPriority** value found on each demand satisfied by the supply is multiplied by the demand quantity, summed together, and then divided by the total demand quantity being satisfied; the **OrderPriority.Value** associated with the closest **PlanningPriority** value that is equal to or lower than that weighted average is then reported. **Default value**: FromInput **Note:** If a scheduled receipt does not satisfy any demands, it is treated as being set to FromInput.	String (Enum)	

Table 7.60: SupplyStatus (Mfg) fields

Field name	Description	Data type	Key
	Note: Planned orders for parts that have PartType.CommitLevel set to either "Medium" or "Low" always use the part's default priority. **Note:** For more information about priorities on supplies, see "Priorities on scheduled receipts" on page 1788 and "Priorities on planned orders" on page 1790.		
PTFLastDueRule	Specifies whether scheduled receipts having this status are considered in planning time fence logic for part sources where the **OrderPolicy.PTFRule** setting is either "LastDueFence", "LastDueLead", "LastDueFenceAll" or "LastDueLeadAll". By default, scheduled receipts inherit this setting from the **SupplyType.PTFLastDueRule** setting referenced by the supply order they belong to, but this field allows overriding that setting on a scheduled receipt basis. Valid values are: • **FromOrder**—Scheduled receipts with this status are included or excluded from the **PTFDate** calculation based on the **SupplyType.PTFLastDueRule** setting used by their supply order. • **Include**—Scheduled receipts with this status are always included in the **PTFDate** calculation for part sources that use any of the "LastDue" planning time fence rules (regardless of the setting on the corresponding supply order).. This means the due date on the part's latest scheduled receipt having this status can potentially be set as the part source's **PTFDate** (assuming it is beyond the part source's fence or lead time value and later than any other scheduled supply from the part source). • **Exclude**—Scheduled receipts with this status are always excluded from the **PTFDate** calculation for part sources that use any of the "LastDue" planning time fence rules (regardless of the setting on the corresponding supply order). This means the due date on the part's latest scheduled receipt having this status will never be set as the part source's **PTFDate** (even if it is beyond the part source's fence or lead time value and later than any other scheduled supply from the part source). **Default value**: FromOrder **Note:** This field was added in Service Update 1908 (prior to this, it was not possible to exclude specific scheduled receipts from the **PTFDate** calculation). For more information, see "Determining the PTFDate" on page 1344	String (Enum)	

Table 7.60: SupplyStatus (Mfg) fields

Field name	Description	Data type	Key
RescheduleRule	Specifies the reschedule rule to be applied to the ScheduledReceipt record (referencing the SupplyStatus table). This value overrides what has been set at the order level using the **SupplyType.ProcessingRule**. Valid values are: • **FromOrder**—supplies will use the rescheduling messaging and logic defined at the order level which is configured using the **SupplyType.ProcessingRule**. • **NonReschedulable**—supplies are assumed to be unable to be rescheduled even if required earlier or later than it is currently scheduled. The **ScheduledReceipt.DueDate** is the date used for netting and explosion purposes. With this setting, a new planned order might be created to cover the demand instead of using the scheduled receipt (depending on when the supply is required). • **Reschedulable**—supplies are assumed to be fully reschedulable. Recommended dates and action messages will be generated where required. **ScheduledReceipt.ReschedDate** is populated with the **ScheduledReceipt.RecommendedDate** and is used for netting and explosion. • **Received**—supply has been received into inventory at its destination (for example, the brand owner's site) and is not included as a supply in Netting calculations. If **SupplyType.ProcessingRule** is set to 'InTransit' or 'InTransitExact', the receipt consumes other scheduled receipts. However, if **SupplyType.ProcessingRule** is set to a value other than 'InTransit' or 'InTransitExact', the receipt is ignored. • **RecommendOnly**—supplies are moved so they align with demands, and may be expedited. RapidResponse recommends a rescheduled date (**ScheduledReceipt.RecommendedDate**), but does not change the effective due date (**ScheduledReceipt.ReschedDate** is populated with **ScheduledReceipt.DueDate**). With this setting, RapidResponse will try to use the scheduled receipt before planning any new planned orders. • **RecommendIfType**—supplies behave the same as the RecommendOnly option, provided the order level setting (**SupplyType.ProcessingRule**) is not set to NonReschedulable or Ignore. • **Scheduled**—supplies are non-reschedulable. If sufficient constraint is not available, the excess balance is applied to the last constraint period, and the constraint used in that period will exceed the amount of constraint available (thus overloading the constraint). This setting is intended for use with supplies that have been scheduled by another system, and which represent a	String (Enum)	

Table 7.60: SupplyStatus (Mfg) fields

Field name	Description	Data type	Key
	firm commitment that has already been agreed to (and allowances made for). Note that with this setting, the supply's **AvailableDate** will be set to its **DueDate** even if there are material shortages . In cases where the **AvailableDateLimit** control uses a setting other than "Due", the **AvailableDate** might in some cases be set earlier than **DueDate** (for example, when the "CalcStart" setting is used and **EffDue** falls on a non-workday, the **AvailableDate** is set to the previous workday). **Default value:** FromOrder		
SortBeforeStart	Specifies how to prioritize supplies. In cases where two supplies have the same DueDate and a sort priority is not able to be determined by the **SupplyType.SortSameDate**, supply consumption priority is determined by comparing the supplies at the line level using SupplyStatus.SortBeforeStart. The lower the value the higher the priority. For a listing of all fields used when sorting scheduled receipts, see "Scheduled receipts usage" on page 1396. **Default value**: 1	Quantity	
SortSameStart	Specifies how to prioritize supply consumption priority. In cases where two supplies have the same DueDate and StartDate, and a sort priority cannot be determined by either the **SupplyType.SortSameDate** or by the **SupplyStatus.SortBeforeStart**, priority is determined by SortSameStart setting. The lower the value the higher the priority. For a listing of all fields used when sorting scheduled receipts, see "Scheduled receipts usage" on page 1396. **Default value**: 1	Quantity	
SplitLateSupply	Provides the option to split the on-time portion of a planned supply from the late portion. In other words, plan a portion of the supply on time even if the entire order cannot be planned on time. This field only affects orders using at least one constraint that is constrained. Valid values are: • **Y**—Plans some portion of this supply on time, if possible, then plans the balance later. If the part source is constrained by a fixed constraint, this value is treated the same as N (order is not split). • **N**—If this entire supply cannot be scheduled on time, then plan a higher priority order now, and this entire supply later. This is the recommended setting. **Default value**: Y	Boolean	

Table 7.60: SupplyStatus (Mfg) fields

Field name	Description	Data type	Key
State	Specifies whether RapidResponse generates dependent requirements, and also affects the lower bound on AvailableDate. **SupplyType.Source** is used in conjunction with the State setting to control the generation and timing of allocations. Valid values are: • **BackflushAndAllocated—**dependent requirements are not generated for this scheduled receipt. Input allocations are treated as due at "past". AvailableDate is never earlier than PlanningCalendars.DataDate.FirstDate. This value differs from ReleasedAndAllocated in that lead time is not incurred if dependent demands are present but satisfied by on hands. • **BackflushButNotAllocated—**dependent requirements are generated for this scheduled receipt, and all dependent requirements are treated as due at "past". AvailableDate is never earlier than Part.PlanningCalendars.DataDate.FirstDate. This value differs from ReleasedButNotAllocated in that lead time is not incurred if dependent requirements are present but all satisfied by on hands. • **Historical**—supply assigned this state is ignored by netting and does not generate dependent requirements (allocations). This value overrides the SupplyStatus.IgnoreSupply field. • **NotReleased**—dependent requirements are generated for this scheduled receipt. AvailableDate is never earlier than PlanningCalendars.DataFirst.FirstDate + lead time (sum of all applicable lead time fields). Lead time is always included in AvailableDate calculations for scheduled receipts with this State, even if no dependent requirements are present. • **NotReleasedAndAllocated**—dependent requirements (allocations) are not generated for this scheduled receipt. AvailableDate is never earlier than the PlanningCalendars.DataDate.FirstDate + LeadTime (sum of all applicable lead time fields). Lead time is always included in AvailableDate calculations for scheduled receipts with this State, even if no dependent requirements are present. • **Planned**—supply assigned this State behaves the same as 'NotReleased' except AvailableDate is never earlier than the PlanningCalendars.RunDate.FirstDate + LeadTime (sum of all applicable lead time fields). All planned orders are treated as if State is 'Planned'. • **ReleasedAndAllocated**—dependent requirements are not generated. AvailableDate is never earlier than PlanningCalendars.DataDate.FirstDate. Lead time is included in AvailableDate calculations for scheduled receipts with this State only if they have dependent	String (Enum)	

Table 7.60: SupplyStatus (Mfg) fields

Field name	Description	Data type	Key
	requirements. Use for orders that have begun production and had components pulled from inventory. • **ReleasedButNotAllocated**—dependent requirements are generated. AvailableDate is never earlier than PlanningCalendars.DataDate.FirstDate. Lead time is included in AvailableDate calculations for scheduled receipts with this State only if they have dependent requirements. Use for orders that have begun production but not had components pulled from inventory. **Default value**: NotReleased		

Table 7.60: SupplyStatus (Mfg) fields

Field name	Description	Data type	Key
TargetAccum	Specifies how scheduled receipt quantities are applied both when generating constraint load, and when accumulating allotments for a **PartSource** with a **Part.SourceRule.AllotmentRule** value of 'Ongoing'. This option is further subject to the setting in the **TargetAccumUsage** field. Valid values are: • **Ignore**—supply assigned this status does not perform accumulation logic in conjunction with the **SourceRule.AllotmentRule** nor does the supply generate load on or consume any constraint. Use this setting if neither constraint nor multi-sourcing logic is used. • **Remaining**—supply assigned this status adds the **ScheduledReceipt.Quantity** (the effective remaining quantity) to **PartSource.ToDateQty** in order to determine the 'current ToDateQty'. The **ScheduledReceipt.Quantity** (the effective remaining quantity) also generates fixed and variable constraint load. • **RemainingNoFixedLoad**—supply assigned this status adds the **ScheduledReceipt.Quantity** (the effective remaining quantity) to **PartSource.ToDateQty** in order to determine the 'current ToDateQty'. The **ScheduledReceipt.Quantity** (the effective remaining quantity) also generates variable constraint load, but does not generate fixed constraint load. • **Order**—supply assigned this status adds the **ScheduledReceipt.TotalQuantity** (the entire quantity of the order) to **PartSource.ToDateQty** in order to determine the 'current ToDateQty'. The **ScheduledReceipt.TotalQuantity** (the entire quantity of the order) also generates constraint load. **Default value:** Ignore **Note:** Applies to scheduled receipts only (planned orders always use the order quantity in calculating constraint load and allotment accumulation).	String (Enum)	

Table 7.60: SupplyStatus (Mfg) fields

Field name	Description	Data type	Key
TargetAccum Usage	This setting controls how the value chosen in the **TargetAccum** field is applied. It allows for scheduled receipt quantities to be used in determining how constraint load is generated, but ignored by the allotment accumulation logic applicable when **SourceRule.AllotmentRule** is "Ongoing" and which influences source selection when there are multiple eligible part sources. For example, scheduled receipt quantities might always generate constraint load, but multi-sourcing logic and hence target allotment accumulation might not be applicable for scheduled receipts until a particular point in the planning horizon. Valid values are: • **AccumulationAndConstraint**—the **TargetAccum** setting is used both in determining how scheduled receipt quantities generate constraint load, and in how those quantities are used when accumulating allotments for "Ongoing" part sources. • **Constraint**—the **TargetAccum** setting is used only in determining how scheduled receipt quantities generate constraint load. Scheduled receipts that use this option are ignored by the allotment accumulation logic applicable to "Ongoing" part sources. **Default value**: AccumulationAndConstraint	String (Enum)	
Value	The string value for this type of SupplyStatus. This value appears in the ScheduledReceipt.Status field. **Default value**: blank string	String	Yes
YieldRule	Specifies whether supplies use the yield ratio and coproduct yield ratio defined on the part source. For example, this setting might be used for scheduled receipts at a later stage of production where the yield factor no longer applies. Valid values are: • **Ignore**—supplies ignore the Yield and CoProductYield ratios defined on the part source. Yield on supplies using this setting is assumed to be 100%. • **Use**—supplies are reduced by the Yield and CoProductYield ratios defined on the part source. **Default value:** Use	String (Enum)	
PartSourceTypes_ PlannedOrder	Set of **PartSourceType** records that reference this SupplyStatus value through their **PlannedOrderSupplyStatus** field.	Set	

Table 7.60: SupplyStatus (Mfg) fields

Field name	Description	Data type	Key
PartSourceTypes_ PlannedOrder ToSR	Set of **PartSourceType** records that reference this SupplyStatus value through their **PlannedOrderToSRSupplyStatus** field.	Set	
PartSourceTypes_ Scheduled Receipts	Set of **ScheduledReceipt** records that reference this SupplyStatus value.	Set	

SupplyType table

The **SupplyType** table defines types for use in the **SupplyOrder** table, as well as the rules for processing scheduled receipts related to **SupplyOrder** records. It's also used in the **PartSourceType** record for defining characteristics for processing of planned orders.

Table 7.61: SupplyType (Mfg) fields

Field name	Description	Data type	Key
Allocation DemandType	Specifies the type of demand (DemandType) that is assigned when generating dependent requirements (allocations) from supplies that are assigned this SupplyType. This field references the DemandType table. For more information, see "DemandType table" on page 715. **Referenced table:** DemandType	Reference	
Allocation ForecastRule	Specifies whether forecasts and sales actuals exploded from scheduled receipts are used in forecast generation and consumption respectively (dependent demands from planned orders are always included in forecast logic). Valid values are: • **Ignore**—Dependent demands from scheduled receipts do not generate forecast demands, nor do they consume other forecast demands. • **Use**—Dependent demands from scheduled receipts with **Order.Type.AllocationDemandType.ProcessingRule** = 'SalesForecast' generate forecast demands for MPS parts. Dependent demands from scheduled receipts with **Order.Type.AllocationDemandType.ProcesingRule** = 'SalesActual' consume forecast demands for MPS parts. **Default value**: Ignore	String (Enum)	

Table 7.61: SupplyType (Mfg) fields

Field name	Description	Data type	Key
BuyInProcess Rule	Specifies whether "Buy" type (purchased) supplies are included in in-process inventory calculations. Valid values are: • **Ignore**—Do not include this "Buy" supply type in in-process inventory calculations. • **IncludeDockToStock**—Includes this "Buy" supply type in in-process inventory calculations (for the duration of dock-to-stock lead time). **Default value**: Ignore	String (Enum)	
Capacity ProcessingRule	Specifies the operation scheduling method applied to supplies (planned and firm) in order to calculate load when using the Capacity Requirements Planning analytic. If this analytic is not being used then this field should be set to 'Ignore'. Valid values are: • **Forward**—scheduling starts with the first operation at the supply planned start date and proceeds forward through the operations. • **Backward**—scheduling starts with the last operation and schedules backward through the operations from the supplies planned completion date. • **Ignore**—operation scheduling is ignored. For open orders, the link to this field is from Scheduled Receipt to SupplyOrder to SupplyType. For planned orders the link to this field is through PartSourceType (PlannedOrderSupplyType) to SupplyType. **Default value**: Forward	String (Enum)	
ControlSet	The control set associated with this SupplyType record. **Referenced table:** ControlSet	Reference	Yes
Description	A description of this type of supply. An explanation of the code in the Value field. **Default value**: blank string	String	

Table 7.61: SupplyType (Mfg) fields

Field name	Description	Data type	Key
LeadTimeRule	Specifies whether lead time calculations use values defined on the part source, or are overridden with values defined on the scheduled receipt. This setting allows lead time overrides to be defined at the order level, and is only valid if **SupplyStatus.LeadTimeOverride** is set to "FromOrder". Valid values are: • **Override**—Lead time values from the scheduled receipt are used in lead time calculations. • **Ignore**—Lead time values from the part source associated with the scheduled receipt are used in lead time calculations. **Default value**: Ignore For more information on overriding lead time on scheduled receipts, see "Lead time overrides from scheduled receipts" on page 1328.	String (Enum)	

Table 7.61: SupplyType (Mfg) fields

Field name	Description	Data type	Key
ProcessingRule	Specifies a processing rule for each scheduled receipt. The processing rule controls, at the order number or header level, both the reschedule recommendations as well as whether the supply is ignored. Valid values are: • **ExplodeOnly**—supply is ignored and considered as non-reschedulable. However, dependent requirements are generated from this type of supply and the **ScheduledReceipt.ReschedDate** (which is populated with the **ScheduledReceipt.DueDate**) is used for explosion. For example, a repair order may require components, but are shipped to the customer and do not get mixed with other supplies. Constraint, if applicable, may be consumed. • **Ignore**—supply is ignored in netting and calculated tables. It does, however, appear in the ScheduledReceipt table. This applies to order number level. • **InTransit**—consumes supply from scheduled receipts having the same part, model, unit, and pool. This consumption occurs in chronological date order, and occurs after any consumption done by 'InTransitExact' scheduled receipts. All scheduled receipts with this setting are also treated as 'non-reschedulable'. • **InTransitExact**—consumes supply from scheduled receipts having the same supplier, routing, part, model, unit, and pool. This consumption occurs in chronological date order. All scheduled receipts with this setting are also treated as 'non-reschedulable'. • **NonReschedulable**—supplies are assumed to be unable to be rescheduled even if required earlier or later than it is currently scheduled. The **ScheduledReceipt.DueDate** is the date used for netting and explosion purposes. With this setting, a new planned order might be created to cover the demand instead of using the scheduled receipt (depending on when the supply is required). • **RecommendOnly**—supplies are moved so they align with demands, and may be expedited. RapidResponse recommends a rescheduled date (**ScheduledReceipt.RecommendedDate**), but does not change the effective due date (**ScheduledReceipt.ReschedDate** is populated with **ScheduledReceipt.DueDate**). With this setting, RapidResponse will try to use the scheduled receipt before planning any new planned orders. • **Reschedulable**—supply can be fully reschedulable. Recommended dates and action messages are generated where required. **ScheduledReceipt.ReschedDate** is populated with the **ScheduledReceipt.RecommendedDate** and is used for netting and explosion. **Default value**: Reschedulable	String (Enum)	

Table 7.61: SupplyType (Mfg) fields

Field name	Description	Data type	Key
PTFLastDueRule	Specifies whether scheduled receipts belonging to orders of this type are considered in planning time fence logic for part sources having an **OrderPolicy.PTFRule** setting of either "LastDueFence", "LastDueLead", "LastDueFenceAll" or "LastDueLeadAll". Valid values are: • **Include**—Supplies of this type are included in the **PTFDate** calculation for part sources that use any of the "LastDue" planning time fence rules. This means the due date on the latest scheduled receipt for the part that belongs to an order of this type can potentially be set as the part source's **PTFDate** (assuming it is beyond the part source's fence or lead time value and later than any other scheduled supply from the part source). • **Exclude**—Supplies of this type are excluded from the **PTFDate** calculation for part sources that use any of the "LastDue" planning time fence rules. This means the due date on the latest scheduled receipt for a part that belongs to an order of this type cannot be set as the part source's **PTFDate** (even if it is beyond the part source's fence or lead time value and later than any other scheduled supply from the part source). **Default value**: Include **Note:** This field was added in Service Update 1908 (prior to this, it was not possible to exclude specific supply types from the **PTFDate** calculation). For more information, see "Determining the PTFDate" on page 1344 **Note:** It is possible to override this setting at the scheduled receipt level using the PTFLastDueRule setting on the **SupplyStatus** table.	String (Enum)	
SortBeforeDate	Specifies how supplies are prioritized when being allocated to demands. RapidResponse sorts supply by comparing values in this field (sorting priority before sorting by DueDate) for reschedulable supplies only (**SupplyType.ProcessingRule** = 'Reschedulable'). For SupplyType values where the ProcessingRule = 'Reschedulable', this field represents the priority in which supplies should be allocated to demands. This must be a positive value and lower values have a higher priority. For a listing of all fields used when sorting scheduled receipts, see "Scheduled receipts usage" on page 1396. **Default value**: 0	Quantity	

Table 7.61: SupplyType (Mfg) fields

Field name	Description	Data type	Key
SortSameDate	Specifies how to sort supplies that have same DueDate. RapidResponse first sorts these supplies by comparing values in this field. This must be a positive value and lower values have a higher priority. For a listing of all fields used when sorting scheduled receipts, see "Scheduled receipts usage" on page 1396. **Default value**: 0	Quantity	
Source	Specifies a source for each SupplyType. The Source value works in conjunction with the BillOfMaterials to control the generation of dependent requirements (allocations) on components. It also works in conjunction with the PartSource, in the case of 'Transfer", to handle inter-site requirements. Valid values are: • **Make**—RapidResponse will look at **BillOfMaterial** records for the Assembly in order to determine which set of Component parts are required to create the supply for this part. Typically, this type of source represents cases where the site itself builds the supply for this part, and is associated with work orders and kitting operations where several different components are assembled together to form a new assembly. • **Buy**—RapidResponse does not generate any further dependent demands for supply using the PartSource. The expectation is that purchase orders are created and communicated to suppliers that manage their own planning. • **Transfer**—Indicates that supply for the part will be provided from another part and site. Unlike Make sources, it does not transfer to multiple components or consider BillOfMaterial records. Instead, supply of the part at the consuming site simply creates a demand for the part at the supplying site. Thus, the expectation is if the consuming site has a need for the part, it will obtain or source what it needs from the supplying site. **Default value:** Make	String (Enum)	
Value	Specifies the text string for this type of supply. This is what appears in records with a SupplyType field. This text string is assigned to each **Order.Id** in the SupplyOrder and ScheduledReceipt tables. **Default value**: blank string	String	Yes
PartSource Types_ PlannedOrder	Set of **PartSourceType** records that reference this SupplyType value through their **PlannedOrderSupplyStatus** field.	Set	

Table 7.61: SupplyType (Mfg) fields

Field name	Description	Data type	Key
PartSource Types_Planned OrderToSR	Set of **PartSourceType** records that reference this SupplyType value through their **PlannedOrderToSRSupplyStatus** field.	Set	
PartSource Types_ SupplyOrders	Set of **SupplyOrder** records that reference this SupplyType value.	Set	

TaskType table

The **TaskType** table contains configurable settings that define processing and calculations at the project level. For example, this table specifies the task's working calendar, and is also used to specify the rules that control how penalties are calculated at the task level.

This table's records can be edited using the **Task Type** worksheet in the **Control Tables for Project Management** workbook included with RapidResponse.

TaskType (ProjMgmt) fields

Field name	Description	Data type	Key
Bonus Accumulation Rule	If there are multiple **BonusScheduleByDate** or **BonusScheduleByInterval** records effective within the bonus period (between the task's **CalcFinishDate** and **BonusDate**), this setting determines how the bonus values on those records are used. Valid values are: • **Cumulative**—bonuses are calculated using the **OneTimeBonus** and **PerIntervalBonus** values defined on each effective entry in the bonus period and applied within their effective ranges only. With this setting there is the possibility for PerInterval bonuses that change over time along with multiple OneTime bonuses. • **FirstInterval**—bonuses are calculated using the **OneTimeBonus** and **PerIntervalBonus** values defined on the first effective entry within the bonus period and applied throughout the entire bonus period. This means either the **BonusScheduleByDate** record with the earliest **EffectiveOutDate** within the bonus period or the **BonusScheduleByInterval** with the highest **Interval** value within the bonus period is used. **Default value:** FirstInterval **Note:** For more information about its usage, see "Bonuses" on page 2196.	String (Enum)	
BonusCalendar	The calendar used when calculating bonuses to be applied to a task. For example, should bonus revenue be earned on a daily or weekly basis. **Referenced table:** Calendar (nullable)	Reference	
BonusRule	Specifies the schedule, if any, to use for calculating task bonuses. This defines the one-time and per interval bonuses that can be earned and applied between the task's calculated finish date and bonus date. Valid values are: • **Date**—bonuses are applied based on dates and values defined in the **BonusScheduleByDate** table. The entries that apply to a given task are set through its **BonusSchedule** reference. • **Interval**—bonus values are applied based on bonus calendar intervals and values defined in the **BonusScheduleByInterval** table. The entries that apply to a given task are set through its **BonusSchedule** reference. • **None**—bonuses cannot be earned by tasks of this type. **Default value:** None **Note:** For more information, see "Bonuses" on page 2196.	String (Enum)	

Field name	Description	Data type	Key
Calendar	The calendar to use when calculating start and finish dates for tasks of this type. If no calendar is specified, then **ProjectType.Calendar** is used instead. **Referenced table:** Calendar (nullable)	Reference	
ControlSet	The control set associated with this **TaskType** record. **Referenced table:** ControlSet	Reference	Yes
Description	A description of this task type.	String	
EfficiencyCurve Rule	Specifies the efficiency curve, if any, applied to resources when assigned to tasks of this type. Efficiency curves are sets of points used to model varying rates of resource efficiency during the completion of a task. For example, they might be used to model tasks on which resources have a lower rate of efficiency initially but then ramp up towards full efficiency as the task progresses. As such, efficiency curves impact values in the **CalcDuration** and **TargetWorkComplete** fields on the **Task** table. Valid values are: • **None**— No efficiency curve is used (a constant rate of efficiency is assumed). • **PointsCurve**—the efficiency curve referenced by the **Task.PointsCurve** value is used. • **Ramp**—a linear efficiency curve is built and used based on the value provided in **Task.Ramp**. **Default value:** None For more information about how this field is used, see "Leveling task resources" on page 2186.	String (Enum)	
FixedCost AccrualRule	Determines when the **Resource.FixedCost** value associated with using a resource is reported on resource loads generated from tasks of this type. This impacts the distribution of fixed cost values as seen in the **ResourceLoad.FixedCost** field. Valid values are: • **Finish**—the entire fixed cost is reported on the date of the last resource load generated from a given task. • **Prorated**—the fixed cost is spread evenly between all dates on which any resource load is generated from a given task. • **Start**—the entire fixed cost is reported on the date of the first resource load generated from a given task. **Default value:** Start	String (Enum)	

Field name	Description	Data type	Key
LevelResources	Indicates if resources can be assigned to a given task in excess of the effective maximum units defined on the resource (from either the **Resource** or **ResourceAvailable** tables). This setting impacts calculated task durations and associated resource loads in cases where a resource is over allocated to a task. Valid values are: • **N**—overloaded resources on a given task are not leveled. The calculated resource loads and task durations ignore resource availability as defined by the **MaximumUnits** field on either the **Resource** or **ResourceAvailable** tables. For example, assume the **ResourceAvailable** table defines a resource as having no units available on a given date where it is assigned to a task. With this setting, load is still assigned to the resource for that date (the resource is seen as overloaded) and the calculated task duration is not impacted. • **Y**—overloaded resources on a given task are leveled. The calculated resource loads and task durations respect resource availabilities as defined by the **MaximumUnits** field on either the **Resource** or **ResourceAvailable** tables. For example, assume the **ResourceAvailable** table defines a resource as being on vacation and having no units available on a given date where it is assigned to a task. With this setting, no load is assigned to the resource for that date (the loads moves to the next date where the resource is seen as available) and the calculated task duration is extended accordingly. **Default value:** N **Note:** For tasks where **Task.DurationType** is set to "FixedDuration", this field is always treated as "N". For more information about how this field is used, see "Leveling task resources" on page 2186.	Boolean	

Field name	Description	Data type	Key
Penalty Accumulation Rule	If there are multiple effective penalty costs defined in either the **PenaltyScheduleByDate or PenaltyScheduleByInterval** table, this setting defines how those costs are applied to tasks throughout the penalty schedule. Valid values are: • **Cumulative**—penalty costs are calculated using the OneTime and PerInterval costs defined on each effective entry on the penalty schedule. This setting allows for PerInterval costs that change over time along with multiple OneTime charges. • **LastInterval**—penalty costs are calculated using the OneTime and PerInterval costs defined on only the last effective entry on the penalty schedule. This setting uses a constant PerInterval cost along with a single OneTime charge. **Default value:** LastInterval For more information about how this field is used, see "Penalties" on page 2191.	String (Enum)	
PenaltyCalendar	The calendar used when calculating penalties applied to a task. For example, should penalty costs be incurred on a daily or weekly basis. **Referenced table:** Calendar (nullable)	Reference	
PenaltyRule	Specifies the schedule, if any, to use for calculating task penalty costs. This defines the one-time and per interval penalty costs that can be incurred and applied between the task penalty date and calculated finish date. Valid values are: • **Date**—penalty values are applied by dates defined in the **PenaltyScheduleByDate** table. The entries that apply to a given task are set through its **PenaltySchedule** reference. • **Interval**—penalty values are applied by calendar intervals defined in the **ProjectScheduleByInterval** table. The entries that apply to a given task are set through its **PenaltySchedule** reference. • **None**—penalties are not are calculated for projects of this type. **Default value:** None For more information about how this field is used, see "Penalties" on page 2191.	String (Enum)	
Value	A unique string identifier for this type of project. This value is referenced from the **Task.Type** field.	String	Yes
Tasks	Set of **Task** records that reference this TaskType value.	Set	

ToleranceProfile table

The ToleranceProfile table identifies each tolerance profile along with the baseline and tolerance calendar used by that profile.

Table 7.62: ToleranceProfile (Mfg) fields

Field name	Description	Data type	Key
BaselineCalendar	The calendar used in identifying the baseline historical demand or supply series. If the AsOfDate value in the HistoricalDemandSeries or HistoricalSupplySeries table belongs to this calendar, than that series is considered a baseline series. **Referenced table**: Calendar	Reference	
ControlSet	The control set associated with this ToleranceProfile record. **Referenced table:** ControlSet	Reference	Yes
Description	An optional description of this tolerance profile.	String	
Tolerance Calendar	The calendar used to calculate tolerance zones used when evaluating the level of forecast change. **Referenced table**: Calendar	Reference	
Value	A unique value used to identify this tolerance profile.	String	Yes
PartCustomers	The set of **PartCustomer** records that reference this ToleranceProfile value.	Set	
PartSuppliers	The set of **PartSupplier** records that reference this ToleranceProfile value.	Set	
Zones	The set of **ToleranceProfileZone** records that reference this ToleranceProfile value.	Set	

ToleranceProfileZone table

The ToleranceProfileZone table defines properties of the tolerance profiles used for historical data analysis. For example, it defines the acceptable increases and decreases allowed when comparing updated data against a baseline historical demand or supply series.

Table 7.63: ToleranceProfileZone (Mfg) fields

Field name	Description	Data type	Key
ControlSet	The control set associated with this ToleranceProfileZone record. **Referenced table:** ControlSet	Reference	Yes
Downside Percentage	The percentage decrease in historical demands or supplies that is acceptable within this zone. A negative value (for example, -1) implies that there is no limit.	Quantity	
ToleranceProfile	A reference to the tolerance profile that this zone belongs to. **Referenced table**: ToleranceProfile	Reference	
Upside Percentage	The percentage increase in historical demands or supplies that is acceptable within this zone. A negative value (for example, -1) implies that there is no limit.	Quantity	
ZoneEndInterval	The number of intervals in the tolerance calendar from the start date to end of this zone. For independent demands, start date is Part.PlanningCalendars.RunDate.FirstDate. For historical demands or historical supplies, start date is the immediately preceding baseline series' AsOfDate. If this value is negative or zero, then the entire entry is ignored. After the last ZoneEndInterval, any amount of increase or decrease is considered acceptable.	Integer	

UnitOfMeasure table

The **UnitOfMeasure** table determines all valid unit of measure codes. By entering records into this table, you can define a relative ratio between two units.

When calculating a statistical forecast, quantities are calculated using **UnitOfMeasure.BaseConversion**. However, a part could have a specific unit of measure conversion rate defined in the **PartUOMConversion** table. Therefore, **UnitOfMeasure.BaseConversion** is ignored if a part has a unit of measure conversion record in the **PartUOMConversion** table.

If **PartUOMConversion** records exist, **UnitOfMeasure.BaseConversion** is ignored when calculating quantities in the following tables:

- **ForecastItemParametersActual**
- **StatisticalForecast**
- **StatisticalForecastDetail**
- **StatisticalForecastDisaggregationRate**

Note: For more information about the PartUOMConversion table, see "PartUOMConversion table" on page 478.

Table 7.64: UnitOfMeasure (Mfg) fields

Field name	Description	Data Type	Key
BaseConversion	Factor to convert quantities in this unit to the base unit. If BaseConversion is less than or equal to zero (<= 0) for any UnitOfMeasure used when converting quantities, no conversion is performed. This avoids divide-by-zero problems. The following formula is used to convert a quantity from **Part.UnitOfMeasure** to a target **UnitOfMeasure**: $\frac{Quantity * Target.UnitOfMeasure.BaseConversion}{Part.UnitOfMeasure.BaseConversion}$	Quantity	
Category	The category associated with this UnitOfMeasure record. **Referenced table:** UnitOfMeasureCategory **Note:** : This field was added in Version 2016.2, Service Update 12.	Reference	
ControlSet	The control set associated with this UnitOfMeasure record. **Referenced table:** ControlSet	Reference	Yes
Description	Additional information about the units of measure or currency. **Default value**: blank string	String	
Rounding Precision	Indicates how much effective quantities on scheduled receipts and planned orders are rounded (this field is applicable only when **OrderPolicy.YieldUsage** is set to an option other than "Ignore" and **OrderPolicy.YieldRoundingUsage** is set to "Use"). After applying the yield factor, the EffQuantity field calculated on scheduled receipts and planned orders for a given part is rounded down to the number of decimal places specified in this field. If only whole order quantities are required, this value should be set to 0. Any value less than 0 is interpreted as 0, and any value greater than 9 is interpreted as 9. **Default value**: 9	Integer	
Value	Unique code for units of measure or currency. **Default value**: EA	String	Yes
ConstraintUnitOfMeasures	The set of **ConstraintUnitOfMeasures** records that reference this UnitOfMeasure value.	Set	
CRPUnitOfMeasures	The set of **CRPUnitOfMeasure** records that reference this UnitOfMeasure value.	Set	

Table 7.64: UnitOfMeasure (Mfg) fields

Field name	Description	Data Type	Key
CurveParameters	The set of **CurveParameter** records that reference this UnitOfMeasure value.	Set	
ForecastItemParameterUOMs	The set of **ForecastItemParameterUOM** records that reference this UnitOfMeasure value.	Set	
LocationCapacities	The set of **LocationCapacity** records that reference this UnitOfMeasure value.	Set	
Parts	The set of **Part** records that reference this UnitOfMeasure value.	Set	
PartSources	The set of **PartSource** records that reference this UnitOfMeasure value.	Set	
PartSuppliers	The set of **PartSupplier** records that reference this UnitOfMeasure value.	Set	
UOMConversions	The set of **PartUOMConversion** records that reference this UnitOfMeasure value.	Set	

Sample records

Assume the following records exist in this table.

Table 7.65: Example of a UnitOfMeasure record

Value	Description	BaseConversion
LB	Pound	1
Ton	Ton	2000

A planned requirement on a part for Quantity of 2000 (Stocking) is considered as an EffQuantity of 1 (purchasing). A purchase order with a Quantity of 1 is considered as an EffQuantity of 2000.

WorkCenterType table

This table identifies the switches and default capacity values for each type of work center.

Table 7.66: WorkCenterType (Mfg) fields

Field name	Description	Data type	Key
Value	The string code for this type of work center. This is what appears in the WorkCenter records. **Default value**: blank string	String	Yes
CapacityMethod	Specifies how to report the machine and labor capacity fields on the daily and weekly work center load records. Valid values are: • **HoursPerDay** — daily/weekly summary of reported capacity for this work center is: *HoursPerDay*NumberOfResource*Efficiency*Utilization*RunRatio* • **DemonstratedCapacity** — daily/weekly summary of reported capacity for this work center will use the DemonstratedCapacity provided. Operation overrides are ignored. • **MaximumCapacity** — daily/weekly summary of reported capacity for this work center will use the MaximumCapacity provided. Operation overrides are ignored. **Default value**: HoursPerDay	Enum	
CapacityReport Limit	Used to define the end of the reporting period for certain work-center based calculations. Represents a number of **PlanningCalendars.TimeUnits** after **RunDate** for reporting the following: • The last date used to include activity for consideration when calculating Capacity-based metrics in RapidResponse. It is recommended this value be the same for all WorkCenterTypes, in all scenarios. Metric results become confusing if the value is different between scenarios. • The latest possible date for reporting effective work center capacity values in the **WorkCenterCapacity** table. • Records showing Capacity, but not Load, in various calculated tables. Not that records are always created up to the last date on which there is Load on the work center. In addition, however, records showing Capacity (and no Load) will be created for every subsequent date up to this limit. **Default value**: 120	Quantity	
ControlSet	The control set associated with this WorkCenterType record. **Referenced table:** ControlSet	Reference	Yes
DefaultHoursPer Day	The total number of working hours in a day at this work center. Only used if there are no capacity records for the work center. **Default value**: 8	Quantity	

Table 7.66: WorkCenterType (Mfg) fields

Field name	Description	Data type	Key
DefaultLabor RunRatio	The number of hours of labor required for one standard hour of run time. This factor is used to convert work center run time load to a labor load. This value is used if there is no effective capacity record for the work center. **Default value**: 1	Quantity	
DefaultLabor SetupRatio	The number of hours of labor required for one standard hour of setup. This factor is used to convert work center setup time load to a labor load. This value is used if there is no effective capacity record for the work center. **Default value**: 1	Quantity	
DefaultMachine RunRatio	The number of hours of machine time required for one standard hour of run time. This factor is used to convert work center run time load to a machine load. This value is used if there is no effective capacity record for the work center. **Default value**: 1	Quantity	
DefaultMachine SetupRatio	The number of hours of machine time required for one standard hour of setup. This factor is used to convert work center setup time load to a machine load. This value is used if there is no effective capacity record for the work center. **Default value**: 1	Quantity	
DefaultNumber OfResources	The number of parallel resources available for scheduling all operations using this work center if there is no applicable Capacity record. This value must be non-negative. This value is used if there is no effective capacity record for the work center. **Default value**: 1	Quantity	
DefaultQueue Time	The pre-operation queue time used for scheduling all operations for this work center unless overridden (see Operation.QueueTimeOverride). This value is the number of hours to wait before setup can begin and must be greater than or equal to zero. Only used if there are no capacity records for the work center. **Default value**: 0	Quantity	
DefaultWaitTime	The post-operation wait time used for scheduling all operations for this work center unless overridden (see Operation.WaitTimeOverride). This value is the number of hours to wait after run time processing ends and must be greater than or equal to zero. Only used if there are no capacity records for the work center. **Default value**: 0	Quantity	
Description	A description of this type of work center. An explanation of the code in the Value field. **Default value**: blank string	String	

Table 7.66: WorkCenterType (Mfg) fields

Field name	Description	Data type	Key
ProcessingRule	Valid values are: • **Ignore** — no information about this work center will be generated on the Load table for any work center referencing this WorkCenterType • **OutsideProcessing** — no information is generated on the Load table but operations around this work center will be scheduled taking into account this operation's duration • **CRP** — generates all information for the Load table **Default value**: CRP	String (Enum)	
WorkCenters	The set of **WorkCenter** records that reference this WorkCenterType value.	Set	

CHAPTER 8: Calculated tables

RapidResponse calculated tables are not editable and hold records generated by RapidResponse calculations. For example, each time RapidResponse recommends a new planned order, RapidResponse creates a new record in the **PlannedOrder** table holding basic details of the order recommended by the netting analytic and a corresponding record in the **CTPPlannedOrder** table reporting order availability details as calculated by the capable-to-promise analytic.

This chapter describes each calculated table in the RapidResponse data model and contains reference information on each field within those tables. Note that a given calculated table might typically have many calculated reference fields that point to other tables that can include multiple references to the same table. However, each table has only one "owner" reference field as noted within the appropriate field descriptions in this chapter. The "owner" reference identifies the specific input table item from which the underlying analytic calculations being reported are triggered. For example, the **WhereConsumedForDemand** table is used to report supplies pegged to a particular independent demand, and its owner is **IndependentDemand**. When enabling item controls on calculated table worksheets, filtering should typically be applied through the "owner" reference in order to limit the number of records that need to be processed by underlying analytic calculations and hence reduce worksheet load times. For more information about filtering and owner references, see the the *RapidResponse Resource Authoring Guide*.

In this chapter, you'll learn about the following:

Note: RapidResponse also contains a number of fields that are populated with calculated data in Input tables. For more information, see "Input tables" on page 171.

Activity table

RapidResponse includes worksheets based on the **Activity** table that combine all OnHand, Supply, and Demand information. These worksheets can be used for projecting inventory balance or generating a complete transaction event report.

The **Activity** table only presents events or activities that are processed by netting (for example, where control table values are not set to ignore it). The description of the **Activity** table is divided between two tables:

- A description of the "Activity (Mfg) fields" on page 942.
- The tables and associated values that the **Activity** table references. See "Tables referenced by the Activity table" on page 951.

Notes:

- If interested in activity type information pertaining to capable-to-promise calculations, see "CTPActivity table" on page 985.

- By default, inactive IndependentDemand records are not included in the **Activity** table. However, these records can be included, as discussed in "Include inactive IndependentDemands in the Activity and CTPActivity tables" on page 2210.

Generation of TimeUnit records

RapidResponse creates Activity records when there is a transaction to report. For example, if an unsatisfied demand is satisfied with available inventory, two Activity records are created. One that shows the demand and the other showing the supply.

Activity records can also be generated based on time buckets. This type of Activity record is called a TimeUnit record. The value of the **Type** field is **TimeUnit**. TimeUnit records are only created if either an ActivityBeat record or an ActivityBeatBeforeRunDate record exists in the **Configuration** table. For information about setting up Configuration records, see "Calculating TimeUnit records" on page 2203.

If an **ActivityBeat** record exists with a value greater or equal to **0**, then the **Activity** table includes TimeUnit records on and after part RunDate. A value of **0** results in one TimeUnit record (or more if multiple model, unit, pool combinations) for the RunDate if there is a CalendarDate entry for that date.

If an **ActivityBeatBeforeRunDate** record exists and has a value greater or equal to **1**, then a TimeUnit record includes records before part RunDate.

TimeUnit records are generated for each Model, Unit, Pool combination netted by the Part.TimeUnit records are also generated for every CalendarDate entry for the **Part.PlanningCalendars.TimeUnits** calendar where:

```
(Part.PlanningCalendars.RunDate.FirstDate - Configuration
[ID=ActivityBeatBeforeRunDate].Value) <= CalendarDate.Value and
(Part.PlanningCalendars.RunDate.FirstDate > CalendarDate.Value)
```

or

```
(Part.PlanningCalendars.RunDate.FirstDate + Configuration
[ID=ActivityBeat].Value) >= CalendarDate.Value and
(Part.PlanningCalendars.RunDate.FirstDate <= CalendarDate.Value)
```

TimeUnit records are never generated for Past or Future date values. The following table shows an example of a TimeUnit record.

Table 8.1: Example of a TimeUnit record

Field	Value
Type	TimeUnit
Part	The part for this record
Model, PegModel	The Model used for netting
Pool, PegPool	The Pool used for netting
StartUnit	The Unit used for netting

Table 8.1: Example of a TimeUnit record

Field	Value
Allocation, Constraint, CTPPlannedOrder, Forecast, IndependentDemand, OnHand, PartSource, PegPart, PlannedOrder, ScheduledReceipt, Supplier	NULL reference
AssociatedDate, AvailableDate, AvailableStartDate DemandDate, DockDate, DueDate, RecommendedDate, ReschedDate, ShipDate, StockDate, SynchronizedDate	The TimeUnit date
AssociatedQty, ATPQuantity, BalanceDelta DemandQty, NewProcessCost, NewPurchasesCost, OnTimeQuantity, SupplyQty	0.0
DemandOrder	<blank>
DemandType (same as for OnHand)	NULL enum
OrderPriority (same as for OnHand)	NULL enum
SupplyType (same as for OnHand)	NULL enum
TransactionSequence	0

Table 8.2: Activity (Mfg) fields

Field name	Description	Data type	Owner
AdjustedDemand Date	For demands, this returns the DemandDate less the part's safety lead time (note that any safety lead time at the part source level is not included). For supplies, thisis the same as RecommendedDate (which considers safety lead time from both the part and part source). **Note:** This field was added in Version 2016.2.	Date	
Allocation	The Allocation record this entry relates to. **Referenced table:** Allocation	Reference	

Table 8.2: Activity (Mfg) fields

Field name	Description	Data type	Owner
AlternatePart	The part the supply or demand activity was created for. This value is different from the Part field value only if that part is interchangeable or globally substitutable with this part as follows: • If the part belongs to a set of interchangeable parts, then Part is the primary part and AlternatePart is the part for the input supply or demand data (or for dependent demands, this is where the demand came from). • If the part belongs to a set of globally substitutable parts, and this record pertains to a supply, then Part is the part that needed the supply and AlternatePart is the part that provided the supply. Otherwise, if this record pertains to a demand, then Part is the part that needed the supply and AlternatePart is the part where the demand came from. **Referenced table**: Part	Reference	
AssociatedDate	The PromiseDate for demands, CalcStartDate for supply, RunDate for on hand.	Date	
AssociatedQty	If the **Type** field is 'DynamicSafety', this is the difference between the revised safety stock quantity and the previous safety stock quantity. Note that records of this type are only generated on dates when there is a dynamic or time-phased safety stock value calculated (or provided) and that value differs from the previous safety stock quantity. If the **Type** field is 'AvailableToPromise', this is **AvailableToPromise.Quantity**. For all **Type** values other than 'DynamicSafety' or 'AvailableToPromise', this field returns 0.		
BalanceDelta	The change in the inventory level due to the original quantity of the activity.	Quantity	
BillOfMaterial	The BOM record that corresponds to NewAllocation or PlannedAllocation records. **Referenced table:** BillOfMaterial	Reference	

Table 8.2: Activity (Mfg) fields

Field name	Description	Data type	Owner
CoByProductSupply	If this record represents supply generated for a co-product or by-product, this field is a reference to the associated CoByProductSupply record (otherwise, this field is NULL). If necessary, the **BillOfMaterial.Type.Product** reference can be used to determine is this record represents supply of a co-product or a by-product. **Referenced table:** CoByProductSupply	Reference	
DemandDate	For supplies, date of the earliest demand matched by netting. For demands, ReschedDate.	Date	
DemandException	If this record represents a demand that was skipped because no planned order could be generated to meet its expiry requirements, this field is a reference to the associated DemandException record. This reference gives additional details on the skipped demand, such as the earliest date that any supply could expire if it were to be used in satisfying that demand. **Referenced table:** DemandException	Reference	
DemandOrder	The order number for independent demand activities.	String	
DemandQty	For demands, the total quantity of the demand, including ShippedQty (SupplyQty will be the shipped quantity or consumed forecast). For supplies, the quantity that has been received. • If Type = 'DynamicSafety', then this field represents the revised safety stock quantity. • If Type = 'AvailableToPromise', then this field is set to AvailableToPromise.SRQuantity.	Quantity	

Table 8.2: Activity (Mfg) fields

Field name	Description	Data type	Owner
DemandType	The DemandType associated with this record. Valid values are: • **OnHand**—first value • **ScheduledReceipt**—first value • **PlannedOrder**—PartSource.Type. PlannedOrderSupplyType.AllocationDemand • **IndependentDemand**—Type • **Allocation**—SRAllocType • **NewAllocation**—SRAllocType • **NewTransferAllocation**—SRAllocType • **PlannedAllocation**—PartSource.Type. PlannedOrderSupplyType.AllocationDemandType • **PlannedTransferAllocation**—PartSource.Type. PlannedOrderSupplyType.AllocationDemand • **Forecast**—type of first Forecast record in bucket. • **AvailableToPromise**—first value **Referenced table:** DemandType	Reference	
DockDate	Date the transaction should be delivered to the receiving dock (calculated from ReschedDate). ReschedDockDate for scheduled receipts. Undefined unless planned order or scheduled receipt.		
DueDate	The date this supply (if it is a supply) is supposed to be available for use (EffDueDate). For demands, the date the demand is needed (based on parent supply ReschedDate if dependent - Allocation.ReschedDate, NewAllocation.DueDate).	Date	
EarliestExpiryDate	The earliest date that supply used to satisfy the demand associated with this record may expire.	Date	
EstimatedExpiry Date	If this record pertains to a supply, this is the date that the Netting analytic calculates that supply will expire. If the supply comes from on hand inventory or an inventory transfer then the supply's **ExpiryDate** value is reported. For all other types of supply, the supply's **EstimatedExpiryDate** value is reported.	Date	

Table 8.2: Activity (Mfg) fields

Field name	Description	Data type	Owner
ExtendedType	Indicates whether this record is associated with an unsourceable demand due to material expiry or is a normal Activity record. Valid values are: • **DemandException**— a record representing an demand that was skipped because supply could not be planned to meet its expiry requirements. Typically, this occurs when RapidResponse is unable to generate a planned order with an expiry date on or after the demand's earliest expiry date. For more information, see "Unsourceable demands and the Activity/CTPActivity tables" on page 1626. • **Normal**—a normal Activity record (does not represent an unsourceable demand due to expiry).	String (Enum)	
FlowToCommon ForecastQuantity	The quantity of this order that consumed forecast. from the common forecast pool (that is, because all of the customer's forecast had already been consumed).	Quantity	
Forecast	The Forecast record associated with this demand (if Activity.Type = 'Forecast'). **Referenced table:** Forecast	Reference	
Independent Demand	Reference to the source of demand. Valid if forecast is placed as Independent Demand on this part. NULL if demand is not from an IndependentDemand record (for example, all dependent demand and ATP). **Referenced table:** IndependentDemand	Reference	
InventoryTransfer	The InventoryTransfer record associated with this Activity record. Valid only if Type is 'InventoryTransfer' or 'InventoryTransferAllocation'. **Referenced table:** InventoryTransfer	Reference	
Model	The model used when netting this record. **Referenced table:** Model	Reference	
OnHand	The OnHand record associated with this record. Valid only if Type is 'OnHand'. **Referenced table:** OnHand	Reference	
OrderPriority	The priority associated with this supply or demand. (for example, Part.Type.DefaultPriority for OnHand). **Referenced table:** OrderPriority	Reference	
Part	The part. **Referenced table:** Part	Reference	Yes

Table 8.2: Activity (Mfg) fields

Field name	Description	Data type	Owner
PartSource	The PartSource from ScheduledReceipt or PlannedOrder. Null if the Activity record does not originate from a ScheduledReceipt or PlannedOrder. **Referenced table:** PartSource	Reference	
PegModel	The model that is applicable to this supply or demand. The field is populated from the source supply or demand record regardless of the value for Part.MUEPoolNettingType.ModelRule. **Referenced table:** Model	Reference	
PegPart	The source of demand if the record describes a dependent demand. This value is NULL for supply records (planned order, scheduled receipt and on hand) as well as independent demand, forecast, and ATP. **Referenced table:** Part	Reference	
PegPool	The pool that is applicable to this supply or demand. This field is populated from the source supply or demand record regardless of the value for Part.MUEPoolNettingType.PoolRule. **Referenced table:** Pool	Reference	
PlannedOrder	The planned order, if any associated with this record: • If this record is a planned order supply for this part, the planned order supply. • If this record is dependent demand from a planned order, the parent (peg) planned order. • Otherwise Null. **Referenced table:** PlannedOrder	Reference	
Pool	This value represents the mapped pool used to satisfy demand. **Referenced table:** Pool	Reference	
Recommended Date	The recommended due date (stock date) for the supply. Same as DueDate if a demand.	Date	
ReschedDate	The revised due date (stock date) after rescheduling the supply. Based on its parent supply's ReschedDate (same as DueDate if a demand).	Date	

Table 8.2: Activity (Mfg) fields

Field name	Description	Data type	Owner
ScheduledReceipt	If this record represents a supply from a ScheduledReceipt, then this field is a reference to that ScheduledReceipt. If this record represents a demand that is an allocation from a ScheduledReceipt, then this field is a reference to that ScheduledReceipt. In all other situations, this field is NULL. **Referenced table:** ScheduledReceipt	Reference	
ShipDate	The date the supply should be shipped from its supplier to meet ReschedDate. Copied from PlannedOrder or ScheduledReceipt. D'undefined' for other types of Activity records.	Date	
StartUnit	The start unit that is applicable to this supply or demand. The field is populated from the source supply or demand record regardless of the value for Part.MUEPoolNettingType.UnitRule.	Integer	
StockUnitQuantity	Represents the supply quantity in inventory unit of measure (UOM) without applying yield or scrap factors. **Note**: **SupplierUOM** applies to **StockUnitQuantity**.	Quantity	
SubstituteSupply	Reference to the substitute supply associated with this record. **Referenced table:** SubstituteSupply	Reference	
Supplier	Reference to the name of the supplier. The supplier of the part. NULL if the supply is from on hand, or if the activity is a demand. **Referenced table:** Supplier	Reference	
SupplyOrder	The order number of ScheduledReceipt activities or the order number from scheduled receipts associated with allocations or new allocations.	String	
SupplyQty	For supplies, the total quantity of the supply (DemandQty will be the received quantity). For demands, the quantity that has been satisfied (shipped or consumed forecast). This quantity is reported in supplier units, and includes inflation for yield. If Type = 'AvailableToPromise', then this field is set to AvailableToPromise.SRQuantity.	Quantity	

Table 8.2: Activity (Mfg) fields

Field name	Description	Data type	Owner
SupplyQtyUnitOfMeasure	Reference to the unit of measure used for the supply quantity that is associated with this record. **Referenced table:** "UnitOfMeasure table" on page 931. **Note:** This field was added in Version 2016.2, Service Update 12.	Reference	
SupplyType	The SupplyType associated with this record. If this record represents a demand record, RapidResponse assigns a blank string to this field. Otherwise, valid values are: • **OnHand**—first value • **ScheduledReceipt—**Type • **PlannedOrder**—PartSource.Type.PlannedOrderSupplyType • **IndependentDemand**—first value • **Allocation**—ScheduledReceipt.Type • **NewAllocation**—ScheduledReceipt.Type • **NewTransferAllocation**—ScheduledReceipt.Type • **PlannedAllocation**—PartSource.Type.PlannedOrderSupplyType • **PlannedTransferAllocation**—PartSource.Type.PlannedOrderSupplyType • **Forecast**—first value • **AvailableToPromise**—first value **Referenced table:** SupplyType	Reference	
Transaction Sequence	Sequence from supply or demand. 0 if not relevant or if there is no corresponding TransactionSequence field in the originating table.	Integer	

Table 8.2: Activity (Mfg) fields

Field name	Description	Data type	Owner
Type	Identifies the type of activity not ignored by netting. Valid values are: • **Allocation** • **AvailableToPromise** • **CoByProductSupply** • **DynamicSafety**(includes any activity from fixed safety stock). • **Forecast** • **IndependentDemand** • **InventoryTransfer** • **InventoryTransferAllocation** • **NewAllocation** • **NewTransferAllocation** • **OnHand** • **PlannedAllocation** • **OrderPointIncrease** • **PlannedTransferAllocation** • **PlannedOrder** • **ScheduledReceipt** • **SubstituteSupply** • **SubstituteAllocation** • **TimeUnit** • **UnplannedSafety** **Default value:** AvailableToPromise	String (Enum)	

Tables referenced by the Activity table

The following table outlines RapidResponse tables referenced by the Activity table. For a complete description of the fields on the Activity table, see the Fields on the "Activity table" on page 940.

AvailableToPromise table

Available to Promise (ATP) is the uncommitted portion of inventory and production for a part. This usually drives sales quotas and delivery time slots for new sales orders (for example, customer orders).

ATP is calculated by daily (TimeUnits) bucketing of the supply records. The first ATP record is on the RunDate and takes into account inventory and all past due supply, as well as supply on the RunDate. After that, there is an ATP record for any workday (for example, from the TimeUnits calendar) for which there is a supply due, unless the ATP value for that date is zero. ATP is calculated using supply at DueDate.

Actual demands (for example, an independent demand whose type's processing rule is SalesActual or Regular) reduce the supply quantity in the closest, or preceding, non-zero ATP bucket(s). The exception is the first bucket (for example, at RunDate) which can go negative. If there is insufficient supply prior to a demand, the closest later supply is allocated. If demand exceeds supply, the ATP in the RunDate bucket will be negative to reflect the shortfall.

Two ATP quantities are calculated; the SRQuantity is calculated with only the scheduled receipts (for example, no planned orders), and Quantity is based on both scheduled receipts and planned orders.

Note: This table is based on results produced by the Netting analytic.

Table 8.5: AvailableToPromise (Mfg) fields

Field name	Description	Data type	Owner
DueDate	When the supply is available to promise.	Date	
Model	The model that applies to this supply. It is set to None if either of the following conditions exist: • Model-Unit Effectivity is not enabled • Part.MUEPoolNettingType.Model Rule is Ignore **Referenced table:** Model	Reference	
Part	The part that is available to promise. **Referenced table:** Part	Reference	Yes
Pool	The pool that applies to this supply. It is set to Unpooled if either of the following conditions exist: • Pool is not enabled • Part.MUEPoolNettingType.Pool Rule is Ignore **Referenced table:** Pool	Reference	

Table 8.5: AvailableToPromise (Mfg) fields

Field name	Description	Data type	Owner
Quantity	The amount of the supply on the due date that is not allocated to actual (real) demand. A negative balance indicates that there is more actual (non-forecast) demand than there is currently open and planned supply (negative balances can only be reported on RunDate).	Quantity	
SRQuantity	Same as Quantity except it only considers Scheduled Receipts as supply. A negative balance indicates that there is more actual (non-forecast) demand than there is currently open supply (negative balances can only be reported on RunDate).	Quantity	
StartUnit	The start unit that applies to this supply. It's set to -1 if either of the following conditions exist: • Model-Unit Effectivity is not enabled • Part.MUEPoolNettingType.UnitRule is Ignore	Integer	

BillOfMaterialFeatureRule table

The **BillOfMaterialFeatureRule** table reports features according to the BOM records where they are used in feature rules. It contains one record for each valid feature included in the **BillOfMaterial.FeatureRule** field on a given record. It also identifies all features that are included in feature rules, but which are not found in the **Feature** table.

Table 8.6: BillOfMaterialFeatureRule (Mfg) fields

Field name	Description	Data type	Owner
BillOfMaterial	A reference to the BOM record on which the feature was included in a feature rule. The **BillOfMaterial.FeatureRule** field can be used to return the actual rule. **Referenced table:** BillOfMaterial	Reference	Yes
Feature	A reference to the name of a feature that was included in a feature rule. Null if the feature name cannot be found in the **Feature.Value** field on any record. **Referenced table:** Feature	Reference	
FeatureGroup Index	Indicates the depth, by position, of the feature within the **BillOfMaterialFeatureRule** field. For example, if the feature name is all that is found in the rule or is included in a simple rule listing potential features separated by "or" clauses, this value reports 0. Conversely, if the feature is contained in the feature rule after two "and" clauses, then this values reports "2".	Integer	

Table 8.6: BillOfMaterialFeatureRule (Mfg) fields

Field name	Description	Data type	Owner
MissingFeatures	A list of all feature names included in the **BillOfMaterial.FeatureRule** field that cannot be found in the **Value** field on any **Feature** record. These might be feature names that were typed incorrectly, or valid feature names that have not yet been added to the **Feature** table. If a feature name is not defined in the **Feature** table, it can still be used by feature BOM logic to determine where dependent demands are generated on configurable end-items, however the feature cannot be used in feature mapping and will not be reported in certain calculated tables.	String	

BlowThroughNewAllocation table

The **BlowThroughNewAllocation** table is a calculated table of the New Allocations for the parts that are bypassing netting at this level (for example, Phantom parts).

Table 8.7: BlowThroughNewAllocation (Mfg) fields

Field name	Description	Data type	Owner
DueDate	Date component is scheduled to be available to the manufacture of the assembly (assembly's StartDate+ BOM offset).	Date	
EarliestExpiryDate	The earliest date that supply can expire if it is to be used in satisfying this demand.	Date	
Model	The model that applies to the allocation. **Referenced table:** Model **Note:** This field was added in Version 2016.2.	Reference	
Part	The Part. **Referenced table:** Part	Reference	Yes
Quantity	Quantity of component needed.	Quantity	
ScheduledReceipt	Reference to the supply record that was exploded from. This is pegging. You can get the parent part and order information through this reference. **Referenced table:** ScheduledReceipt	Reference	
StartUnit	The start unit that applies to this allocation. It may differ from the ScheduledReceipt.StartUnit due to demand splitting.	Integer	

BlowThroughPlannedAllocation table

The **BlowThroughPlannedAllocation** table is a calculated table of the Planned Allocations for the parts that are bypassing netting at a given level (for example, Phantom parts).

Table 8.8: BlowThroughPlannedAllocation (Mfg) fields

Field name	Description	Data type	Owner
DueDate	The date that the component is scheduled to be available to the manufacturer of the assembly (assembly's StartDate + BOM offset).	Date	
EarliestExpiry Date	The earliest date that supply can expire if it is to be used in satisfying this demand.	Date	
Model	The model that applies to this allocation. It is set to None if the parent part is not netted by model. **Referenced table:** Model	Reference	
OrderPriority	The priority associated with this demand. **Referenced table:** OrderPriority	Reference	
Part	The Part. **Referenced table:** Part	Reference	Yes
PegDueDate	The date of the planned order or ATP. You can determine the exact planned order using this date and the PegPart (the RapidResponse data model will not generate two planned orders or ATPs on the same day).	Date	
PegPart	Pegging back to the part that the planned order or ATP is on. **Referenced table:** Part	Reference	
PegPartSource	The PartSource record used to create the planned order. PartSource can be used to find PartSource.Supplier and PartSource.SupplierPart (that were formerly found on the Part table.) **Referenced table:** PartSource	Reference	
Pool	The pool that applies to this allocation. It is set to Unpooled if the parent part is not netted by pool. **Referenced table:** Pool	Reference	
Quantity	Quantity of component needed.	Quantity	
Transaction Sequence	Transaction sequence from supply.	Integer	

Table 8.8: BlowThroughPlannedAllocation (Mfg) fields

Field name	Description	Data type	Owner
StartUnit	The start unit that applies to this allocation. It may differ from the PlannedOrder.StartUnit due to demand splitting.	Integer	
Type	The demand type from the PlannedOrder supply type or from a planning bill (see BOMType and PartType control tables). A copy of all the PlannedAllocation records that bypassed the netting of a part because of phantom logic. **Referenced table:** DemandType	Reference	

BOM_MUECUMLead table

The **BOM_MUECUMLead** table supports the Model-Effectivity and Unit-Effectivity analytics. This table is only available for use if you have enabled Model-Unit Effectivity.

If the BOM record is in effect (using date effectivity), this table is populated with the consolidated records of the Component.Part_MUECumLead table. Otherwise, no records are created. Records are consolidated by unique combinations of UseModel (when UseModel = False, then Model will = None), Model, StartUnit and EndUnit.

The Model, FirstEffectiveUnit, LastEffectiveUnit, and Type.MUERule of the BillOfMaterial record and the ModelRule, UnitRule of the Component.MUEPoolNettingType determine which records of the **Component.MUECumLead** are used for the consolidation.

If the BOM is a phantom (**BOMType.BlowThrough** = **Y** or **Component.DependentDemandUsage** = **BlowThrough)**, then the resulting CumLeadTime is adjusted by that of the component.

Table 8.9: BOM_MUECUMLead (Mfg) fields

Field name	Description	Data type	Owner
BillOfMaterial	The BillOfMaterial record for which the cumulative lead time applies. **Referenced table:** BillOfMaterial	Reference	Yes
CumLead	The cumulative lead time for the BillOfMaterial record for this Model and StartUnit / EndUnit range.	Quantity	
EndUnit	The effective ending unit (calculated using the BOMType.EffectivityRule**)**.	Integer	
Model	The model for which the cumulative lead time applies. **Referenced table:** BillOfMaterial	Reference	
MultiSiteCum LeadTime	The multi-site cumulative lead time for the BillOfMaterial record for this Model and StartUnit / EndUnit range.	Quantity	

Table 8.9: BOM_MUECUMLead (Mfg) fields

Field name	Description	Data type	Owner
StartUnit	The effective starting unit (calculated using the BOMType.EffectivityRule).	Integer	
UseModel	Indicates whether the above model is used for netting. Valid values are: • **True**—the model is used for netting • **False**—the model is ignored for the calculation of the CumLeadTime	Boolean	

CoByProductSupply table

The **CoByProductSupply** table reports Netting calculations, such as due dates and quantities, for co-product and by-product supplies that are triggered by production of a primary product.

Co-products are manufactured together with a primary product and typically have similar components and process similarities as the primary product. By-products are generated as a result of, and residual to, production of the primary product but they have some value.

Because they are generated from production of another product, co-product and by-product supplies do not explode to dependent components nor do they consume any constraint. As well, order priority is not reported on these types of supplies as they are assumed to have the same priority as the primary product's supply.

Table 8.10: CoByProductSupply (Mfg) fields

Field name	Description	Data type	Owner
BOM	The bill of material record that associates the primary product (assembly) with the co-product or by-product (component) whose supply is being reported here. The **BOM.Type.ProductType** reference can be used to show whether this is a co-product or by-product supply. **Referenced table:** BillOfMaterial	Reference	
DemandDate	The date of the demand matched to this supply by Netting calculations.	Date	
DueDate	The date when this supply is due. This is calculated starting from the DueDate of the primary product supply and adding the LeadTimeOffset value defined on the BOM record that associates the primary product with this co-product or by-product.	Date	

Table 8.10: CoByProductSupply (Mfg) fields

Field name	Description	Data type	Owner
EarliestExpiry Date	The earliest date that any supplies used to satisfy dependent demands generated from this supply can expire. Typically, this is determined from the latest **EarliestExpiryDate** found on a demand that Netting calculations determine this supply will satisfy. Otherwise, if there are no consuming demands, this value is calculated from the by adding the number of expiry calendar intervals defined in **Part.MinimumShelfLife** to the due date. Calculated from **StartDate** (adjusted for the primary part's expiry calendar), and then adjusted by **BOM.LeadTimeOffset** (in terms of the primary part's time units calendar) as well as **BOM.IntervalToExpiryOffset** (in terms of the primary part's expiry calendar). For non-expiry parts (**PartType.ExpiryRule** is set to "Ignore"), this field always reports "Past".	Money	
EstimatedExpiry Date	The date that the Netting analytic calculates this supply will expire. Used to determine which demands this supply can potentially be used to satisfy (supply is only eligible for use if it is on ot before the demand's **EarliestExpiryDate**). This date might be different from the actual expiry date reported in the **CTPCoProductSupply** table which takes supply availabilities into account. Non-expiry parts (**PartType.ExpiryRule** is set to "Ignore") always return a value of "Future".	Money	
Model	The model that applies to this supply. It is set to None if either of the following conditions exist: • Model-Unit Effectivity is not enabled • Part.MUEPoolNettingType.ModelRule is Ignore **Referenced table**: Model	Reference	
NeedQty	The amount of this co-product or by-product supply that is actually needed to satisfy demand for the part.	Quantity	
Part	A reference to the co-product or by-product part that this supply is for. **Referenced table:** Part	Reference	Yes
Pool	The pool that applies to this supply. It is set to Unpooled if either of the following conditions exist: • Pool is not enabled • Part.MUEPoolNettingType.PoolRule is Ignore **Referenced table:** Pool	Reference	

Table 8.10: CoByProductSupply (Mfg) fields

Field name	Description	Data type	Owner
PrimaryPart	A reference to the primary product whose planned order or scheduled receipt generated this co-product or by-product supply. **Referenced table:** Part	Reference	
PrimaryPlanned Order	A reference to the planned order for the primary product that generated this co-product or by-product supply. NULL if the primary product supply was a scheduled receipt. **Referenced table:** PlannedOrder	Reference	
Primary Scheduled Receipt	A reference to the scheduled receipt for the primary product that generated this co-product or by-product supply. NULL if the primary product supply was a planned order. **Referenced table:** ScheduledReceipt	Reference	
PrimarySupply Type	Indicates the type of the primary product's supply that triggered the generation of this co-product or by-product. Valid values are: • PlannedOrder • ScheduledReceipt	String (Enum)	
Quantity	The amount of this co-product or by-product supply. This is calculated by multipling the primary product supply's effective quantity (EffQuantity) by the QuantityPer defined on the BOM record that associates the primary product with this co-product or by-product (and then taking the absolute value of that result).	Quantity	
StartDate	The date when production of the supply should be started. This is set to the StartDate of the primary product supply that triggered this order.	Date	
StartUnit	The start unit number that applies to this supply. It is set to -1 if either of the following conditions exist: • Model-Unit Effectivity is not enabled • Part.MUEPoolNettingType.UnitRule is 'Ignore'	Integer	

Conflict table

The **Conflict** table identifies and reports details of task scheduling conflicts. A conflict indicates that a task cannot be scheduled in a manner that satisfies all limitations placed on it such as scheduling rules, predecessor/successor relationships, constraints, and material order requirements. These conflicts might lead to the generation of project plans and dates that are not necessarily desirable or achievable and should therefore be reviewed.

Task conflicts can occur in situations where a limitation placed on a task causes its dates to move in the opposite direction from which the task is being scheduled. Typically, this might be because of a task constraint or material order requirement. Task scheduling is set by the **ProjectType.ScheduleRule** setting on the project the task belongs to (either "FromStart" or "FromFinish"). For tasks in projects that are scheduled from their start date, a conflict results when a constraint attempts to move the task start/finish dates back and earlier than they would otherwise be. For tasks in projects that are scheduled from their finish date, a conflict results when a constraint attempts to move the task start/finish dates forward and later than they would otherwise be.

This table contains one record for each conflict found on an automatically scheduled task along with details of the constraint or material order requirement that caused the conflict. The **Project Plan** workbook included with RapidResponse also identifies any (primary) conflicts found on tasks within a project.

Table 8.11: Conflict (ProjMgmt) fields

Field name	Description	Data type	Owner
Constraint	If the scheduling conflict is caused by a task constraint, indicates the type of constraint (for example, "MustStartOn"). Otherwise, a value of "None" is returned.	String (Enum)	
Date	The date associated with the source of the task conflict as follows: • If the conflict was caused by a task constraint, then the date on which the task would have started if there was no constraint is reported. • If the conflict was caused by a material order link, then the supply or demand available date plus any applicable offset is reported • If the conflict was caused by the project run date, then the date the task would start on to respect all other scheduling parameters is reported. • If the conflict was caused by an actual start date on a task, then the date on which the task should start to satisfy the other scheduling parameters (such as, predecessor tasks) is reported. • If the conflict was caused by an actual or expected finish date on a task, then the date on which the task should finish to satisfy other scheduling parameters (such as, successor tasks) is reported.	Date	
Demand	If the conflict was caused by a demand order link, this is a reference to that **TaskDemandLink** record. The **IndependentDemand** record associated with the required material can also be accessed through this reference. Otherwise, null. **Referenced table:** TaskDemandLink	Reference	
Project	A reference to the project that the conflicted task belongs to. **Referenced table:** Project	Reference	Yes

Table 8.11: Conflict (ProjMgmt) fields

Field name	Description	Data type	Owner
Source	Indicates the scheduling parameter that led to the conflict reported on this record. For example, conflicts might typically be caused by task constraints or material order requirements. Valid values are: • **ActualFinishDate**—the conflict was caused by an actual finish date specified on the task. For example, in a project scheduled from finish, the ActualFinishDate might force the task to finish after a dependent successor task has already started. • **ActualStartDate**—the conflict was caused by an actual start date specified on the task. For example, in a project scheduled from the start, the ActualStartDate might force the task to start before a required predecessor task has been able to finish. • **Constraint**—the conflict was caused by a task constraint. The constraint date is honored and takes precedence over the other scheduling parameters. • **Demand**—the conflict was caused by the availability of an independent demand. The dates determined by the other scheduling parameters are honored and take precedence over the demand requirement. • **ExpectedFinishDate**—the conflict was caused by an expected finish date specified on the task. For example, in a project scheduled from finish, the ExpectedFinishDate might force the task to finish after a dependent successor task has already started (applicable to FixedDuration tasks only). • **RunDate**—the conflict was caused by the RunDate in a date-driven project. The RunDate is honored and takes precedence over the other scheduling parameters (for example, a task might be forced to finish after a dependent successor task or after the project finish date in order to respect the RunDate). • **Supply**—the conflict was caused by the availability of a scheduled receipt. The dates determined by the other scheduling parameters are honored and take precedence over the supply requirement.	String (Enum)	
Supply	If the conflict was caused by a supply order link, this is a reference to that **TaskSupplyLink** record. The **ScheduledReceipt** record associated with the required material can also be accessed through this reference. Otherwise, null. **Referenced table:** TaskSupplyLink	Reference	

Table 8.11: Conflict (ProjMgmt) fields

Field name	Description	Data type	Owner
Task	A reference to the task that has a conflict. **Referenced table:** Task	Reference	
Type	Indicates the phase in task scheduling where the conflict was detected. Because project tasks can be scheduled either from the project start date or the project finish date (based on a setting in the **ProjectType** table), conflicts caused by certain scheduling parameters can exist in either direction. Valid values are: • **Primary**—Indicates that the task conflict exists as the project is currently scheduled. For example, if the project has a **ProjectType.ScheduleRule** value of "FromStart", then this value indicates the conflict occurs when scheduling tasks from the project start date. This type of conflict typically requires investigation. • **Secondary**—Indicates a conflict that does not present itself as the project is currently scheduled. For example, if the project has a **ProjectType.ScheduleRule** of "FromStart", then this value indicates the conflict would occur if scheduling tasks from the project finish date. This type of conflict can typically be ignored.	String (Enum)	

ConsensusForecast table

The **ConsensusForecast** table contains the consensus forecast generated from the sales and operations planning process in RapidResponse. Each record in this table contains a calculated forecast amount for a part and customer combination on a given forecast date.

Forecast quantities in this table are calculated as a weighted combination of different forecast category quantities from the **ForecastDetail** table and event-based forecast adjustments on a given date. The weight assigned to a particular forecast category when calculating the consensus forecast for a part and customer combination is determined by the **ConsensusForecastWeight** field in one of the following tables:

- **HistoricalDemandHeaderTimePhasedAttributes**—this table stores time-phased forecast category weights per part customer. If it contains a record for a given forecast category and part customer combination, with an effective date range that includes the forecast date, then the category weight is taken from this table.
- **HistoricalDemandHeaderRollingWeight**—this table stores forecast weights to be used for a specific header and horizon combination when using rolling forecast weights. If a header has existing **HistoricalDemandHeaderTimephasedAttributes** records, this table is ignored.
- **HistoricalDemandHeader**—this table stores forecast category weights specific to a part customer when there is no requirement for time-phasing. If it contains a record for a given forecast category and part customer combination, and there is no effective record for that combination in either the **HistoricalDemandHeaderTimePhasedAttributes** table or the **HistoricalDemandHeaderRollingWeight** table, then the category weight is taken from this table.

- **HistoricalDemandCategoryRollingWeight**—this table stores forecast weights to be used for a specific category and horizon combination when using rolling forecast weights. If a header has existing **HistoricalDemandHeaderTimephasedAttributes** **HistoricalDemandHeaderRollingWeight**, or **HistoricalDemandHeader** records, this table is ignored.
- **HistoricalDemandCategory**—this table stores default forecast category weights to be used when there is no requirement for customer-specific weights. If there is no effective record for a given forecast category and part customer combination in of the **HistoricalDemandHeaderTimePhasedAttributes**, **HistoricalDemandHeaderRollingWeight**, **HistoricalDemandCategoryRollingWeight**, or **HistoricalDemandHeader** tables, then the category weight for the part customer is taken from this table.

Note that only categories with a **ConsensusForecastWeight** value greater than zero are used in calculating the consensus forecast values reported in this table. For example, if **ConsensusForecastWeight** was set to 1 for the Statistical forecast category and 0 for all other forecast categories, then the consensus forecast would be set to the statistical forecast value. Similarly, if **ConsensusForecastWeight** was set to 0.5 for the Finance forecast category, 0.4 for the Sales forecast category, and 0.2 for the Marketing forecast category, then the consensus forecast would be a summation of fifty-percent of the finance forecast, forty-percent of the sales forecast, and twenty-percent of the marketing forecast.

The **ConsensusForecast** table is used to drive supply planning in RapidResponse based on the consensus forecast generated during the sales and operations process. Consensus forecast quantities are subsequently reported in the **Forecast** table (subject to any forecast spreading logic) with a **ForecastSource** value of "ConsensusForecast". Availability of the forecast is given in the **CTPForecast** table, and details of all supplies used to satisfy the forecast can be seen in the **WhereConsumedForForecast** table.

If the **ForecastDetail** table contains a record for a given date, part, and customer where **Header.Category.Type.ProcessingRule** is set to "ForecastOverride" or "ReBalancingForecastOverride", then that record value is automatically reported in this table in the **OverrideQuantity** field instead of the calculated consensus forecast.

Note: ConsensusForecast records can only be generated for parts where the **PartType.ProcessRule** value is set to either "MPS" or "MPSConfig".

Table 8.12: ConsensusForecast (Mfg) fields

Field name	Description	Data type	Owner
CalculatedQuantity	The original calculated consensus forecast for this date. For example, this value might be different than the actual consensus forecast value reported in the Quantity field in cases where an override or adjustment was used for the consensus forecast.	Quantity	
Date	The date of this consensus forecast.	Date	

Table 8.12: ConsensusForecast (Mfg) fields

Field name	Description	Data type	Owner
EarliestExpiryDate	The earliest date that a supply can expire if it is to be used in satisfying this forecasted demand. For parts not configured for expiry, this field is always set to "Past". Calculated based on the demand **Date** and the **MinimumShelfLife** value from either the **TimePhasedPartCustomerAttributes** table (if used) or else the **PartCustomer** table (if > 0) or else the **Part** table. If provided, **ExpiryOffset** values on either the **TimePhasedPartCustomerAttributes** or **PartCustomer** tables are also used in this calculation.	Date	
EffectiveAllotment Override	A reference to the AllotmentOverride record (or Null) used to manually reserve component supply to the consensus forecast demand for this part and customer combination. **Referenced table:** AllotmentOverride	Reference	
EffectiveMinimum ShelfLife	For parts configured for expiry, this field represents the number of expiry calendar intervals to be added to the forecast date in order to determine its EarliestExpiryDate. For a given part and customer combination, this field is populated with the value from the **MinimumShelfLife** field value on either the **TimePhasedPartCustomerAttributes** table (if used), or the **PartCustomer** table (if > 0), or else the **Part** table.	Integer	
EffectivePriority	The order priority associated with this consensus forecast. For a given part and customer combination, this field is populated with the value from the **OrderPriority** field on either the **TimePhasedPartCustomerAttributes** table (if used), or else the **PartCustomer** table **Referenced table:** OrderPriority	Reference	

Table 8.12: ConsensusForecast (Mfg) fields

Field name	Description	Data type	Owner
EffectiveUnitPrice	The unit price effective for this forecast. This is typically useful in determining the revenue associated with the forecast. The calculated value in this field is based on the **EffectiveUnitPrice** value(s) found on the underlying **ForecastDetail** record(s) that make up the consensus forecast quantity. If there is only one associated **ForecastDetail** record, then its **EffectiveUnitPrice** is used here. Otherwise, if there are multiple associated **ForecastDetail** records, then this field contains a weighted average of the **EffectiveUnitPrice** values on those underlying records (each is given a weight relative to the quantity it contributes to the overall consensus forecast quantity). Currency conversions on this field use the **Date** field's conversion rate. **Note:** If the values that contribute to determining **ForecastDetail.EffectiveUnitPrice** are negative, the value reported in both **ForecastDetail.EffectiveUnitPrice** and **ConsensusForecast.EffectiveUnitPrice** is set to zero. For information about how the value in the **ForecastDetail.EffectiveUnitPrice** field is determined, see "EffectiveUnitPrice" on page 286.	Money	
OverrideQuantity	Reports override value made to the consensus forecast when generating the demand plan (typically, done using the **S&OP Consensus Demand Planning** workbook). This type of override originates from **ForecastDetail** records where the **HistoricalDemandCategoryType.ProcessingRule** is set to "ForecastOverride".	Quantity	
Part	The part this forecast applies to. **Referenced table**: Part	Reference	Yes
PartCustomer	The combination of the part and customer this forecast applies to. **Referenced table:** PartCustomer	Reference	
Quantity	The amount of the consensus forecast for this date.	Quantity	
Rebalancing Adjustment Quantity	Reports adjustments made to either the calculated consensus forecast or the forecast override quantity (if specified) when rebalancing the demand plan to the supply plan. The adjustments originate from **ForecastDetail** records where the **HistoricalDemandCategoryType.ProcessingRule** is "RebalancingAdjustment".	Quantity	

Table 8.12: ConsensusForecast (Mfg) fields

Field name	Description	Data type	Owner
Rebalancing OverrideQuantity	Reports overrides made to the consensus forecast when rebalancing the demand plan to the supply plan (typically, done using the **S&OP Demand Supply Balancing** workbook). This type of override takes precedence over any other override or adjustment values and originates from **ForecastDetail** records where the **HistoricalDemandCategoryType.ProcessingRule** is "ReBalancingForecastOverride".	Quantity	

ConsensusForecastDetail table

The **ConsensusForecastDetail** table identifies and reports details of **ForecastDetail** records that are used for generating the consensus forecast value for a particular part and customer during the sales and operations planning process and reported in the **ConsensusForecast** table. For example, it might report details of multiple weighted forecast categories that contribute to the consensus forecast on a given date along with the quantity that each of those categories contributes to the consensus forecast value.

Note: If a **ForecastDetail** record is affected by an event-based adjustment, it is reported in the analogous **EventConsensusForecastDetail** table instead of the **ConsensusForecastDetail** table. For more information, see "EventConsensusForecastDetail table" on page 1039.

Table 8.13: ConsensusForecastDetail(Mfg) fields

Field name	Description	Data type	Owner
Consensus Forecast	A reference to the **ConsensusForecast** record. This returns the calculated consensus forecast for a particular part and customer combination on a given forecast date. **Referenced table:** ConsensusForecast	Reference	
Date	The date from the **ForecastDetail** record, rounded down to the nearest date on the **PartCustomer.EffectiveDisaggregation Calendar**. **Note:** This field was added in Version 2016.2, Service Update 3.	Date	

Table 8.13: ConsensusForecastDetail(Mfg) fields

Field name	Description	Data type	Owner
Effective Quantity	The amount from the referenced **ForecastDetail** record that contributes to the consensus forecast total. This value will be different from the value in **ForecastDetail.Quantity** in cases where the consensus forecast is a weighted sum combining values from different forecast categories. Thus, the sum of all values in this field for each referenced record in the **ConsensusForecast** table should equate to the **ConsensusForecast.Quantity** value. In some cases, this field might return zero. For example, if the referenced **ForecastDetail** record represents either a negative forecast adjustment or a forecast stream whose quantity was reduced to zero by an adjustment.	Quantity	
Forecast Detail	A reference to a **ForecastDetail** record. This returns the forecast quantity and date for a particular part, customer, and forecast category combination that are contributing to the consensus forecast quantity. In cases where a forecast override or forecast rebalancing override is used, only the associated **ForecastDetail** record for that override is referenced in this table (that is, any other forecast details that contributed to the value found in **ConsensusForecast.CalculatedQuantity** are ignored in this table). **Referenced table:** ForecastDetail	Reference	
Part	The part whose consensus forecast this record pertains to. **Referenced table:** Part	Reference	Yes

ConsensusForecastRollingHorizonWeight table

The **ConsensusForecastRollingHorizonWeight** table reports the weight that is applied to a forecast category in a given horizon when using rolling forecast weights to create the consensus demand plan. The results are based on values from the **HistoricalDemandCategoryRollingWeight** and **HistoricalDemandHeaderRollingWeight** tables. It also reports the source of the forecast weight value. See "Consensus forecast category weights" on page 2073.

Note: If a header has existing **HistoricalDemandHeaderTimephasedAttributes** records, this table is ignored. Therefore, to use the rolling forecast weights, you need to make sure to delete any exsiting **HistoricalDemandHeaderTimephasedAttributes** records.

The **ConsensusForecastRollingHorizonWeight** table supports the Demand Planning application in RapidResponse. Values in this table are reported in the **S&OP Demand Planning Ratios** workbook. For more information about the Demand Planning application, see the RapidResponse Applications Guide.

This table was added in Version 2016.2, Service Update 12.

Table 8.14: ConsensusForecastRollingHorizonWeight (Mfg) fields

Field name	Description	Data type	Owner
Source	Indicates the source of the weight value that was used to calculate the consensus forecast. Valid Values are: • **HistoricalDemandHeaderRollingWeight**—Indicates that the consensus forecast weight was set using the **HistoricalDemandHeaderRollingWeight** table. • **HistoricalDemandHeader**—Indicates that the consensus forecast weight is from the **HistoricalDemandHeader** table. **HistoricalDemandCategory**—Indicates that the consensus forecast weight is from the **HistoricalDemandCategory** table. • **HistoricalDemandCategoryRollingWeight**— Indicates that the consensus forecast weight is from **HistoricalDemandCategoryRollingWeight** table.	Enum	
Weight	The value of the forecast weight that is associated with this category or header during a specific horizon.	Quantity	
Header	A reference to the header. **Reference table**: HistoricalDemandHeader	Reference	Yes
Horizon	A reference to the horizon. **Referenced table**: ConsensusForecastRollingHorizon	Reference	

ConsensusForecastWeightByHeader table

The **ConsensusForecastWeightByHeader** table reports the resulting consensus forecast weights by headers. The values that are reported are used by **ConsensusForecast** calculations. The results are based on the **ConsensusForecastWeight** that is set using one of the following input tables:

- HistoricalDemandCategory
- HistoricalDemandCategoryRollingWeight
- HistoricalDemandHeader
- HistoricalDemandHeaderRollingWeight
- HistoricalDemandHeaderTimePhasedAttributes

The **ConsensusForecastWeightByHeader** table is used if the **ProcessingRule** field on the **HistoricalDemandCategoryType** table is set to "Forecast", indicating that the historical demand category will be used towards calculating the consensus forecast. If the **HistoricalDemandHeaderTimePhasedAttributes** table contains a record for a given forecast category and part customer combination, with an effective date range that includes the forecast date, then it is used to generate the consensus forecast.

Note: For more information about consensus forecast weight calculations, see "Consensus forecast category weights" on page 2073.

Table 8.15: ConsensusForecastWeightByHeader (Mfg) fields

Field name	Description	Data type	Owner
Date	The date in the disaggregation calendar, which defines the periods that orders can be disaggregated into.	Date	
Header	A reference to the part customer and forecast category combination this set of values applies to. **Referenced table:** HistoricalDemandHeader	Reference	Yes
Weight	The weight for the header.	Quantity	

ConstraintLoad table

This table reports load on a Constraint from supplies. This shows when the Constraint was requested. Exactly one ConstraintLoad record is generated for each supply referencing an active Constraint except no ConstraintLoad record is generated for supplies where Load is 0, TargetAccum= **Ignore** or where Constraint.Type.ProcessingRule = **Unconstrained**.

Table 8.16: ConstraintLoad (Mfg) fields

Field name	Description	Data type	Owner
Constraint	The name of the Constraint. **Referenced table:** Constraint	Reference	Yes
CTPPlanned Order	The CTP planned order generating this load (Null if a scheduled receipt). **Referenced table:** CTPPlannedOrder	Reference	
Date	The date load is placed on the constraint. Either the ship date or start date associated with the later of material start date and resched date of the supply, normalized to the beginning of the constraint period.	Date	
IsPlanned	Indicates whether this load is from a planned order (Y) or scheduled receipt (N).	Boolean	
Load	The quantity of load placed on this constraint by this supply. Note that no unit of measure conversion is applied between supply units and Constraint units.	Quantity	

Table 8.16: ConstraintLoad (Mfg) fields

Field name	Description	Data type	Owner
Model	The model of the supply creating the load. **Referenced table:** Model	Reference	
Pool	The pool of the supply creating the load. **Referenced table:** Model	Reference	
Scheduled Receipt	The immediate scheduled receipt generating this load (Null if a planned order). **Referenced table:** ScheduledReceipt	Reference	
Source Constraint	The SourceConstraint that produced this load. **Referenced table:** SourceConstraint	Reference	
SupplyPart	The part whose supply is creating this Load. **Referenced table:** Part	Reference	

ConstraintSpreadLoad table

The **ConstraintSpreadLoad** table is generated for constraints where the Type.ProcessingRule is either Constrained, LoadOnly, or CumMax. It reports load that is scheduled, but can overload the available constraint. This table is similar to the **ConstraintLoad** table, except that a single supply can have several ConstraintSpreadLoad records (as opposed to one record per supply in ConstraintLoad).

ConstraintSpreadLoad is normally applied between the earliest date that constraint can be applied to the supply and the latest date that constraint can be applied and still meet the supply's ReschedDate. The constraint is initially applied up to the amount of constraint available (allowing for any previously allocated constraint). Any load that cannot be satisfied to complete the order for its ReschedDate is spread evenly between the early constraint date and the late constraint finish.

For more information about how constraint is spread across periods, see "ConstraintLoad" on page 1646 and "ConstraintSpreadLoad" on page 1646.

Table 8.17: ConstraintSpreadLoad (Mfg) fields

Field name	Description	Data	Owner
Constraint	The constraint the spread load record refers to. **Referenced table:** Constraint	Reference	Yes
CTPPlannedOrder	The planned order generating the load. This field is null if a scheduled receipt is generating the load. **Referenced table:** CTPPlannedOrder	Reference	
Date	The date the load is planned for this constraint. This considers load from other orders and constraint availability. Date is always reported as the start of the constraint period for the referenced constraint.	Date	

Table 8.17: ConstraintSpreadLoad (Mfg) fields

Field name	Description	Data	Owner
IsPlanned	Indicates whether this load is from a planned order or a scheduled receipt. Values are: • **Y**—Load is from a planned order. • **N**—Load is from a scheduled receipt.	Boolean	
Load	The quantity of load placed on the constraint by this supply in this period.	Quantity	
Model	The model of the supply creating the load. **Referenced table:** Model	Reference	
Overloaded	Indicates if *any* constraint associated with the supply is overloaded (does not have sufficient remaining capacity). Valid values are: • Y • N **Note:** For scheduled receipts where **Status.RescheduleRule = 'Scheduled'**, a value of **Y** indicates that one of the constraints is overloaded by the scheduled receipt.	Boolean	
Pool	The pool of the supply creating this load. **Referenced table:** Pool	Reference	
ScheduledReceipt	The immediate scheduled receipt generating this load. This field is null if a planned order is generating the load. **Referenced table**: ScheduledReceipt	Reference	
SourceConstraint	The source constraint that produced this load. **Referenced table**: SourceConstraint	Reference	
SupplyPart	The part whose supply is creating the load. **Referenced table:** Part	Reference	

ConstraintUsed table

This table reports when load is allotted to each supply that uses a Constraint. One or more ConstraintUsed records are generated for each ConstraintLoad record. This table supports the Constraint Manager application.

Table 8.18: ConstraintUsed (Mfg) fields

Field name	Description	Data type	Owner
Constraint	The name of the Constraint. **Referenced table:** Constraint	Reference	Yes
ConstraintLoad	The Constraint load being allocated. **Referenced table:** ConstraintLoad	Reference	
ConsumptionSequence	During constraint scheduling, the order that constraint is set to be consumed.	Integer	
Date	The date this amount of Constraint is allotted to this supply. Date is the beginning of the period that Constraint is available. It can be the period including the load or a subsequent period.	Date	
Load	The quantity of load satisfied in this period.	Quantity	
Overloaded	Indicates if *any* constraint associated with the supply is overloaded (does not have sufficient remaining capacity). Valid values are: • Y • N **Note:** For scheduled receipts where **Status.RescheduleRule = 'Scheduled'**, a value of **Y** indicates that one of the constraints is overloaded by the scheduled receipt.	Boolean	
ProductionCycleNumber	The cycle number that the constraint is used in. For example, a cycle number of 2 means that the constraint is used in the second cycle of the production wheel. Default value: 0	Integer	
ProductionWheel	A reference to the production wheel associated with this ConstraintUsed record. Reference table: ProductionWheel	Reference	

Table 8.18: ConstraintUsed (Mfg) fields

Field name	Description	Data type	Owner
Type	The type of constraint used during constraint scheduling. Valid values are: **Fixed**—the constraint associated with SourceConstraint.FixedConstraintFactor **Variable**—the constraint associated with SourceConstraint.ConstraintFactor **CampaignFixed**—the constraint associated with SourceConstraint.CampaignFixedConstraintFactor **MajorSetup**—the constraint associated with ProductionGroup.MajorSetup **MajorCleanup**—the constraint associated with ProductionGroup.MajorCleanup **MinorChangeOver**—the constraint associated with ProductionGroup.MinorChangeOver	Enumeration	

CostOfGoodsSold table

The **CostOfGoodsSold** table stores records created by RapidResponse for each supply quantity that satisfies an originating demand (independent or dependent). **CostOfGoodsSold** records provide extended costs on supplies apportioned to originating demands. This includes all sources of demand, excess scheduled receipts, excess on hand, and excess supply from planned orders due to lot sizing. For information about how RapidResponse calculates **CostOfGoodsSold** records, see "Cost of goods sold calculations" on page 1503.

Table 8.19: CostOfGoodsSold (Mfg) fields

Field name	Description	Data type	Owner
AlternatePart	The part the supply activity was created for. This value is different from the Part field value only if that part is interchangeable or globally substitutable with this part as follows: • If the part belongs to a set of interchangeable parts, then Part is the primary part and AlternatePart is the part for the input supply data (or for dependent demands, this is where the demand came from). • If the part belongs to a set of globally substitutable parts, and this record pertains to a supply, then Part is the part that needed the supply and AlternatePart is the part that provided the supply. **Referenced table**: Part	Reference	
CTPCoByProduct Supply	A reference to the CTP details for the co-product or by-product associated with this record. Costs for co-products and by-products come from the corresponding primary product in proportion to the percentage split associated with the co-product or by-product supply. This field is NULL unless supply comes from a co-product or by-product. **Referenced table:** CTPCoByProductSupply	Reference	
CTPForecast	A reference to the driver part's consensus forecast demand (as generated during the sales and operations planning process in RapidResponse) that is satisfied by this supply. NULL unless DriverType = 'ConsensusForecast'. **Referenced table:** CTPForecast	Reference	
CTPPlanned Order	A reference to the consumed planned order. This field is Null unless the supply is a planned order. **Referenced table:** CTPPlannedOrder	Reference	
CTPSubstitute Supply	The CTP Substitute Supply for this record. **Referenced table:** CTPSubstituteSupply	Reference	
DriverAvailable Date	The date the driver is available.	Date	
DriverDueDate	The DueDate of the driver for this demand.	Date	
DriverPart	The part driving the demand that consumes the supply. **Referenced table:** Part	Reference	
DriverQuantity	The quantity of the driving demand.	Quantity	

Table 8.19: CostOfGoodsSold (Mfg) fields

Field name	Description	Data type	Owner
DriverScheduled Receipt	A reference to the scheduled receipt ultimately driving this requirement. This field is Null unless DriverType is a ScheduledReceipt. **Referenced table:** ScheduledReceipt	Reference	
DriverType	Indicates the source of this demand. Valid values are: • **CoByProductSupply**—this supply is used to satisfy a co-product or by-product generated from a primary product supply. • **ConsensusForecast**—this supply is used to satisfy consensus forecast demand generated during the sales and operations planning process. • **Forecast**—this supply satisfies an unconsumed forecast. • **IndependentDemand**—this supply satisfies an independent demand. The IndependentDemand reference is valid. • **InventoryTransfer**—this supply satisfies an inventory transfer. • **OnHand**—this supply is excess on hand inventory not used in satisfying any demand. • **ScheduledReceipt**—this supply satisfies a scheduled receipt. The DriverScheduledReceipt reference is valid. • **PlannedOrder**—this supply satisfies a supply with no corresponding demand (therefore excess due to safety or planned order lot sizing). The Driver references are invalid.	String	
Independent Demand	A reference to the independent demand driving this requirement. This field is Null unless DriverType is IndependentDemand or Forecast. **Referenced table:** IndependentDemand	Reference	
Inventory Transfer	The inventory transfer satisfying this demand. **Referenced table:** InventoryTransfer	Reference	
LaborCost	Extended labor cost. This field is zero if SupplySource is OnHand, InKit, or None. Currency conversions on this field use the **DueDate** field's conversion rate, except in the following cases: • If the supply is an on hand supply, the **Date** field of the on hand record is used. • If the supply is an InKit, the Part.PlanningCalendars.RunDate.FirstDate value is used.	Money	

Table 8.19: CostOfGoodsSold (Mfg) fields

Field name	Description	Data type	Owner
MaterialCost	Extended material cost for this supply. Material costs are calculated for inventory supplies, in-kit supplies, purchased supplies, and allocated scheduled receipts. Currency conversions on this field use the **DueDate** field's conversion rate, except in the following cases: • If the supply is an on hand supply, the **Date** field of the on hand record is used. • If the supply is an InKit, the Part.PlanningCalendars.RunDate.FirstDate value is used.	Money	
Model	The model used when netting this record. It is set to None if either of the following conditions exist: • Model-Unit Effectivity is not enabled • Part.MUEPoolNettingType.ModelRule control value is Ignore. **Referenced table:** Model **Note:** This field is set to the first record in the Model table. The first record in the Model table should always be None.	Reference	
NeedDate	The date when this supply is needed to achieve on-time delivery for the driver.	Date	
NeedQuantity	The amount of this supply required to meet the demand.	Quantity	
OnHand	The inventory record satisfying this demand. Null unless the supply is OnHand. **Referenced table:** OnHand	Reference	
OverheadCost	Extended overhead cost. Zero if SupplySource is OnHand, InKit, or None. Currency conversions on this field use the **DueDate** field's conversion rate, except in the following cases: • If the supply is an on hand supply, the **Date** field of the on hand record is used. • If the supply is an InKit, the Part.PlanningCalendars.RunDate.FirstDate value is used.	Money	

Table 8.19: CostOfGoodsSold (Mfg) fields

Field name	Description	Data type	Owner
OverheadCost2	Secondary extended overhead cost. Zero if SupplySource is OnHand, InKit, or None. Currency conversions on this field use the **DueDate** field's conversion rate, except in the following cases: • If the supply is an on hand supply, the **Date** field of the on hand record is used. • If the supply is an InKit, the Part.PlanningCalendars.RunDate.FirstDate value is used.	Money	
Part	The part whose supply is consumed. **Referenced table:** Part	Reference	Yes
PartSource	The part source used by the supply. **Referenced table:** PartSource	Reference	
Pool	The pool used when netting this record. It's set to Unpooled if either of the following conditions exist: • Pool is not enabled. • Part.MUEPoolNettingType.PoolRule control value is Ignore. **Referenced table:** Pool **Note:** This field is set to the first record in the Pool table. The first record in the Pool table should always be Unpooled.	Reference	
Scheduled Receipt	A reference to the scheduled receipt that is consumed. This field is Null if the supply is not a scheduled receipt. **Referenced table:** ScheduledReceipt	Reference	
SplitSupply Available	If incremental availability calculations are turned on for the supply, this represents the date a portion of the supply is available. If incremental availability calculations are turned off for the supply, this represents the date when the entire supply is available (except for cases where a planned order is split based upon constraint allocation).	Quantity	
SubstituteGroup	A reference to the substitute group associated with the supply. Null unless the supply is for a substitutable component under a given bill of material structure, or associated with a substitutable allocation under a given scheduled receipt. **Referenced table:** SubstituteGroup	Reference	

Table 8.19: CostOfGoodsSold (Mfg) fields

Field name	Description	Data type	Owner
SupplyAvailable Date	The date when the entire supply is available.	Date	
SupplyDemand	The supply and demand being reported by this record. **Referenced table:** SupplyDemand	Reference	
SupplyDueDate	The effective due date of the supply being consumed.	Date	
SupplyQuantity	Total quantity of the supply.	Quantity	
SupplyQuantity UnitOfMeasure	Reference to the unit of measure used for the supply quantity that is associated with this record. **Referenced table:** "UnitOfMeasure table" on page 931. **Note:** This field was added in Version 2016.2, Service Update 12.	Reference	
SupplyStartUnit	The start unit used when netting this record. It is set to -1 if either of the following conditions exist: • Model-Unit Effectivity is not enabled • Part.MUEPoolNettingType.UnitRule control value is Ignore.	Quantity	
SupplySource	The source of this supply record. Valid values are: • **CoByProductSupply**—supply is a co-product or by-product. • **CTPPlannedOrder**—normal planned order. • **InKit**—supply from InKit quantity on an allocation. • **InventoryTransfer**—supply is an inventory transfer. • **None**—no supply is available to satisfy this demand. • **OnHand**—supply is in on hand inventory. • **ScheduledReceipt**—normal scheduled receipt. • **SubstituteSupply**—supply comes from a substitute part.	String (Enum)	
WhereConsumed	The WhereConsumed record corresponding to this record. **Referenced table:** WhereConsumed	Reference	

CostRollUp table

The **CostRollUp** table stores rolled-up cost results, which are calculated based on effective bill components and effective part sources for every part. In cases where a part has multiple effective part sources at the highest priority, RapidResponse prorates the cost according to the target values on the relevant part sources.

The table description below uses the term **descendants**. This term includes all components that appear below a specific part assembly (including components of components and so on). Components that arise through transfer part sources are also included.

The term **effectively purchased** is used in the description of the **MaterialCostOnly** field. Effectively purchased parts do not have components. They are either purchased parts, parts with a make part source but no effective bill components, or parts with a transfer part source for which the transfer part name and site matches the part name and site. For information about how RapidResponse calculates **CostRollUp** records, see "Cost roll-up calculations" on page 1511.

Table 8.20: CostRollUp (Mfg) fields

Field name	Description	Data type	Owner
FirstDate	The beginning of the date range (inclusive) for which these rolled-up costs apply.	Date	
FirstUnit	The first unit to which these rolled-up costs apply.	Integer	
LaborCost	Rolled-up labor costs for this part, based on labor costs for all descendants of this part, including the part itself. Currency conversions on this field use the **FirstDate** field's conversion rate.	Money	
LastDate	The end of the date range (inclusive) for which these rolled-up costs apply.	Date	
LastUnit	The last unit to which these rolled-up costs apply.	Integer	
MaterialCostOnly	Rolled-up material purchase costs for this part. Based on all effectively purchased descendants of this part, including the part itself (assuming it's effectively purchased). Currency conversions on this field use the **FirstDate** field's conversion rate.	Money	
Model	The model to which these costs apply. **Referenced table:** Model	Reference	
OverheadCost	Rolled-up overhead costs for this part, based on overhead costs for all descendants of this part, including the part itself. Currency conversions on this field use the **FirstDate** field's conversion rate.	Money	
OverheadCost2	Rolled-up secondary overhead costs for this part, based on secondary overhead costs for all descendants of this part, including the part itself. Currency conversions on this field use the **FirstDate** field's conversion rate.	Money	

Table 8.20: CostRollUp (Mfg) fields

Field name	Description	Data type	Owner
Part	The part for which rolled-up costs are calculated. **Referenced table:** Part	Reference	Yes

CriticalPath table

The **CriticalPath** table can be used to identify all tasks that are on the critical path for a given project, as well as all gated tasks regardless of whether they are on a project's critical path.

Tasks on the critical path are those that directly impact the project finish date, and hence can potentially push out the project finish date if they finish late or pull in the project finish date if they can finish early. The **Critical** field can be used to find all tasks that are on a project's critical path.

Gated tasks are those whose completion is impacted by other items such as predecessor tasks, material order requirements, or constraints. If there are multiple items gating a given task in a project, then multiple records are reported in this table for that task and project combination. The **Source** field can be used to find all tasks that are gated, and other fields in this table used to provide details of the gating task and/or order.

Table 8.21: CriticalPath (ProjMgmt) fields

Field name	Description	Data type	Owner
Critical	Indicates whether the task is on the critical path for the project. Valid values are: • Y • N	Boolean	
GatingDemand	A reference to an independent demand that is gating the task reported on this record. This reference is valid only when the **Source** value is 'Demand'. **Referenced table:** IndependentDemand	Reference	
GatingSupply	A reference to a scheduled receipt that is gating the task reported on this record. This reference is valid only when the **Source** value is 'Supply'. **Referenced table:** ScheduledReceipt	Reference	
GatingTask	A reference to another task that is gating the task reported on this record. This reference is valid only when the **Source** value is 'Task'. **Referenced table:** Task	Reference	
Project	A reference to the project that the task being reported in this record pertains to. **Referenced table:** Project	Reference	Yes

Table 8.21: CriticalPath (ProjMgmt) fields

Field name	Description	Data type	Owner
Task	A reference to the task this record pertains to. This will be either a task that is on the critical path for its project, or that is gated by another task or material dependency, or both. **Referenced table:** Task	Reference	
Source	Indicates the type of dependency, if any, that is gating the task reported on this record and placing it on the project's critical path. Valid values are: • **Constraint**—task completion is impacted by a date-based constraint placed on the task. • **Demand**—task completion is impacted by the availability of a required demand order. • **None**—task completion is not impacted by any other tasks or material dependencies. • **Task**—task completion is impacted by the completion of another task. • **Supply**—task completion is impacted by the availability of a required supply order.	String (Enum)	

CTPActivity table

This table reports results of CTP calculations. It also shows AvailableDate and related information.

This table contains one record per supply, unless either:

- the incremental availability option is turned on for a supply in which case multiple records might be generated for that supply (as a result of component availability, constraint availability, or both).
- some portion of the supply will expire, in which case a second record is added with an ExtendedType field value of "Expiring" (The original record of this supply will have its ExtendedType field value of "Normal"). The second record reports the expiring quantity in the DemandQty field, the negative of the expiring quantity in the BalanceDelta field and has a SupplyQty equal to 0.

Activity table comparison

This table has some similarities to the Activity table. However, while the Activity table should be used when the reporting of planning actions is required, the CTPActivity table should be used when capable-to-promise results are required. Among the main differences between the Activity and CTPActivity tables:

- Although netting may run for a part, thus producing records in the Activity table, CTP may not run for that same part and therefore no CTPActivity table records would be produced. In particular, if a part has a recursive BOM structure below it, CTP calculations will not be performed even though Netting calculations are.
- Reschedulable scheduled receipts where none of the supply is needed are not reported in the CTPActivity table, though they are reported in the Activity table.

- The CTPActivity table reports supplies as they are used in capable-to-promise calculations to satisfy demands. In cases where there is an especially large variation in the quantities of supplies or demands (such as, 1,000,000:1), the quantity of a particular supply or demand reported in this table might be slightly different than the actual supply or demand quantity.

Note: If attribute-based planning is used to impact the allotment of supply to demand, all relevant demand and supply attributes at the part level can be reported on records in this table using the `Attribute<*>` syntax. Note that any demand attributes without a mapping in the **AttributeMap** table are excluded. For more information on the *Attribute*<*> syntax, see the *RapidResponse Resource Authoring Guide*).

Table 8.22: CTPActivity (Mfg) fields

Field name	Description	Data type	Owner
Adjusted Demand Date	For demands, this returns the DemandDate less the part's safety lead time (note that any safety lead time at the part source level is not included). For supplies, thisis the same as RecommendedDate (which considers safety lead time from both the part and part source). **Note:** This field was added in Version 2016.2	Date	
Allocation	The Allocation record this entry relates to. **Referenced table:** Allocation	Reference	
AlternatePart	The part the supply or demand activity was created for. This value is different from the Part field value only if that part is interchangeable or globally substitutable with this part as follows: • If the part belongs to a set of interchangeable parts, then Part is the primary part and AlternatePart is the part for the input supply or demand data (or for dependent demands, this is where the demand came from). • If the part belongs to a set of globally substitutable parts, and this record pertains to a supply, then Part is the part that needed the supply and AlternatePart is the part that provided the supply. Otherwise, if this record pertains to a demand, then Part is the part that needed the supply and AlternatePart is the part where the demand came from. **Referenced table**: Part	Reference	
AssociatedDate	The PromiseDate for demands, CalcStartDate for supply, PlannedOrder.DueDate for dependent demands from planned orders, and RunDate for on hand.	Date	

Table 8.22: CTPActivity (Mfg) fields

Field name	Description	Data type	Owner
ATPQuantity	The quantity of this supply (0 if a demand) that is available to promise (allocated to excess, sales forecast, or production forecast).	Quantity	
AvailableDate	The date the entire supply is available, unless the incremental availability option is turned on for the supply in which case this represents the date a segment of the supply is available.	Date	
AvailableStart Date	If incremental availability is turned off for the supply, this field represents the date when work is expected to start on the supply (all materials and the first portion of constraint are available). If incremental availability is turned on for the supply, this field represents the date when work is expected to start on the segment of the supply (some set of materials and the first portion of constraint are available). This field is calculated from AvailableDate if there is no active constraint.	Date	
BalanceDelta	The change in the inventory level due to the original quantity of the activity.	Quantity	
Constraint	The Constraint whose insufficient capacity means the supply will not be ready for its MaterialAvailableDate. If this supply is not late, this field is empty. **Referenced table:** Constraint	Reference	
CTPCoByProduct Supply	Reference to the CTP cobyproduct associated with this supply. **Referenced table:** CTPCoByProductSupply	Reference	
CTPForecast	Reference to the consensus forecast that is the source of this demand. **Referenced table:** CTPForecast	Reference	
CTPPlanned Order	Reference to the CTP planned order record that is this supply or is the immediate parent of dependent demands from a planned order. **Referenced table:** CTPPlannedOrder	Reference	
CTPSubstitute Supply	Reference to the CTP substitute supply associated with this record. **Referenced table:** CTPSubstituteSupply	Reference	

Table 8.22: CTPActivity (Mfg) fields

Field name	Description	Data type	Owner
DemandDate	For supplies, date of the earliest demand matched by netting (DemandDate). For demands, same as Activity.DueDate.	Date	
Demand Exception	If this record represents a demand that was skipped because no planned order could be generated to meet its expiry requirements, this field is a reference to the associated DemandException record. This reference gives additional details on the skipped demand, such as the earliest date that any supply could expire if it were to be used in satisfying that demand. **Referenced table:** DemandException	Reference	
DemandQty	For demands, the total quantity of the demand, including ShippedQty (SupplyQty will be the shipped quantity or consumed forecast). For supplies, the quantity that has been received. If the record has an **ExtendedType** value of "Expiring", this field contains the amount of the supply that will not be used before its expiry date.	Quantity	
DemandType	The DemandType associated with this record. **Referenced table:** Demand	Reference	
DockDate	Date the transaction should be delivered to the receiving dock (calculated from ReschedDate). ReschedDockDate for scheduled receipts. Undefined unless planned order or scheduled receipt.	Date	
DueDate	The date this supply (if it is a supply) is supposed to be available for use (EffDueDate). For demands, the date the demand is needed (based on parent supply ReschedDate if dependent - Allocation.ReschedDate, NewAllocation.DueDate). **Note:** For self-allocations, this field is always set to 'Past'. For more information about self-allocations, see "Self-allocations" on page 1424.	Date	
EarliestExpiry Date	If this record represents a demand, this is the earliest date that supply used to satisfy that demand may expire. If this record represents a supply, this is the earliest date that supply may expire if it is to be used in satisfying its dependent demands (taken from the latest EarliestExpiryDate of any demands it satisfies in Netting calculations.)	Date	

Table 8.22: CTPActivity (Mfg) fields

Field name	Description	Data type	Owner
Estimated ExpiryDate	If this record pertains to a supply, this is the date that the Netting analytic calculates that supply will expire and uses in determining which demands it can potentially supply satisfy. Note that this value might be different than the actual expiry date which is reported in the ExpiryDate field and considers all supply availabilities in its calculation. If the supply comes from on hand inventory or an inventory transfer then the supply's **ExpiryDate** value is reported here. For all other types of supply, the supply's **EstimatedExpiryDate** value is reported.	Date	
ExpiryDate	The data that the supply associated with this record will expire (is no longer usable).	Date	
ExpiryStart Date	Date on which to start supply expiry date calculations for assemblies having a **PartType.ExpiryRule** of "DependentStart (based on earliest ExpiryStartDate rolled up from a component supply). This field is calculated for all expiring parts that are either designated as limiting components or contain limiting components in their product structure. Otherwise, this field is set to "Future". For more information about how supply expiry start dates are used, see "DependentStart" on page 1618.	Date	

Table 8.22: CTPActivity (Mfg) fields

Field name	Description	Data type	Owner
ExtendedType	Indicates whether this record is associated with a special extended type or is a normal CTPActivity record. Valid values are: • **DemandException**— a record representing demand that was not met because supply could not be sourced to meet its expiry requirements. Typically, this occurs when RapidResponse is unable to generate a planned order with an expiry date on or after the demand's earliest expiry date. For more information, see "Unsourceable demands and the Activity/CTPActivity tables" on page 1626. • **Expiring**—a record representing the expiring portion of a supply (that is, the portion of a supply that will not be used before its expiry date). For records of this type, the DemandQty field contains the expiring quantity, the SupplyQty field is always set to zero (0), and the BalanceDelta field contains the inverse (negative) of the expiring quantity. For more information, see "Expiring quantities and the CTPActivity table" on page 1624. • **Normal**—a normal CTPActivity record (does not represent an expiry demand exception or the expiring portion of a supply). • **PushTransfer**—a record representing planned order supplies for a part that are arriving at a destination site earlier than requested. This occurs when the pre-built supply at the sourcing site exceeds the maximum inventory level that is set for the part. **Note:** This value was added in Version 2016.2.	String (Enum)	
Forecast	The Forecast record associated with this demand (if Activity.Type =Forecast). **Referenced table:** Forecast	Reference	
HoldEndDate	The date on which the supply, or portion of supply, reported on this record can actually be used without violating the minimum safety stock level (represented as a higher priority safety stock demand). This field is only populated if the part's **SafetyStockPolicy.CTPHoldRule** setting is "Use", incremental availability is enabled for the part, and some or all of the supply needed to be held from a demand it was allotted to in order to maintain safety stock. **NOTE**: This field was added in Version 2016.2, Service Update 18.	Date	

Table 8.22: CTPActivity (Mfg) fields

Field name	Description	Data type	Owner
HoldStartDate	The date from which the supply, or portion of supply, reported on this record should be held in order to respect a higher priority safety stock demand. In other words, this is the date that the minimum safety stock level (represented as higher priority safety stock) would be violated if the supply allotment were not held. This field is only calculated if the part's **SafetyStockPolicy.CTPHoldRule** setting is "Use", incremental availability is enabled for the part, and some or all of the supply needed to be held from a demand it was allotted to in order to maintain safety stock. **NOTE**: This field was added in Version 2016.2, Service Update 18.	Date	
Independent Demand	Reference to the source of demand. NULL if demand is not from an IndependentDemand record (for example, all dependent demand). **Referenced table:** IndependentDemand	Reference	
Inventory Transfer	The InventoryTransfer record associated with this CTPActivity record. Valid only if Type is 'InventoryTransfer' or 'InventoryTransferAllocation'. **Referenced table:** InventoryTransfer	Reference	

Table 8.22: CTPActivity (Mfg) fields

Field name	Description	Data type	Owner
LateBeyondTolerance Quantity	The amount of the late demand that is available outside of tolerance. That is, the amount of the demand that is later than its due date plus the number of **ForecastCalendar** intervals specified in the **Part.UnsatisfiedDemandTolerance** field. For example, if **ForecastCalendar** is "Month" and **UnsatisfiedDemandTolerance** is "0", this reports the amount of the demand that is available later than the end of the week in which it is due. Similarly, if **UnsatisifedDemandTolernace** were set to "2", this would return the amount of the demand that was available later than the end of the second month after which it was due. When using on-time reallocation logic (where **PartType.OnTimeAllocationRule** is set to "ImproveWithTolerance"), supply quantities that are allotted to demands beyond lateness tolerance can be reallocated to try and improve the on-time quantity on late demands (with the potential side effect of also making the available date on those late worse than they otherwise would be). Note that this field returns 0 (zero) for all supply records, as well as any demands that are on time or not later than tolerance. **Note**: This field was added in Version 2016.2, Service Update 27, and is calculated regardless of the part's **OnTimeAllocationRule** setting.	Quantity	
Model	The model used when netting this record. **Referenced table:** Model	Reference	
NewProcessCost	Standard labor and overhead cost of planned orders to complete this order. Currency conversions on this field use the **DueDate** field's conversion rate, except in the following cases: • If the supply is an on hand supply, the **Date** field of the on hand record is used.	Money	
NewPurchases Cost	Cost of new purchases required in order to complete this order (through all levels of the bill). Currency conversions on this field use the **DueDate** field's conversion rate, except in the following cases: • If the supply is an on hand supply, the **Date** field of the on hand record is used.	Money	
OnHand	The OnHand record associated with this record. Valid only if Type is 'OnHand'. **Referenced table:** OnHand	Reference	

Table 8.22: CTPActivity (Mfg) fields

Field name	Description	Data type	Owner
OnTimeQuantity	The quantity of this activity that could be completed on or before its ReschedDate if it was possible to split the order.	Quantity	
OrderPriority	The priority associated with this supply or demand (Part.Type.DefaultPriority for OnHand). **Referenced table:** OrderPriority	Reference	
Part	The part this record relates to. **Referenced table:** Part	Reference	Yes
PartSource	The PartSource from ScheduledReceipt or PlannedOrder. Populated if the Activity record is based on a ScheduledReceipt, PlannedOrder, or dependent demand. Otherwise, Null. **Referenced table:** PartSource	Reference	
PegModel	The model that is applicable to this supply or demand. The field is populated from the source supply or demand record regardless of the value for Part.MUEPoolNettingType.ModelRule.	String	
PegPart	The source of demand if the record describes a dependent demand. This value is NULL for supply records (planned order, scheduled receipt and on hand) as well as independent demand, forecast, and ATP. **Referenced table:** Part	Reference	
PegPool	The pool that is applicable to this supply or demand. This field is populated from the source supply or demand record regardless of the value for Part.MUEPoolNettingType.PoolRule. **Referenced table:** Pool	Reference	
Pool	The pool used when netting this record. **Referenced table**: Pool	String	

Table 8.22: CTPActivity (Mfg) fields

Field name	Description	Data type	Owner
PushTransferID	A unique integer identifier for pre-built supply that was transferred earlier than needed (pushed) from a sourcing site to a distribution site as a result of the pre-built supply exceeding the maximum inventory level that was set for the part. This field only applies to parts that are enabled for push planning (have **DistributionPlanningRule.ProcessingRule** set to "Use". Additionally if **DistributionPlanningRule.SupplyShareRule** is set to "All", then this field is populated for all transfers from the sourcing site to distribution site (including late supplies). This is regardless of the maximum inventory level being exceeded and whether the supply was actually pushed earlier than needed. **Note:** This field was added in Version 2016.2.	Integer	
Recommended Date	The recommended due date (stock date) for the supply. Same as DueDate if a demand or planned order.	Date	
ReschedDate	The revised due date (stock date) after rescheduling the supply. Based on its parent supply's ReschedDate (same as Activity.DueDate if a demand.)		
Scheduled Receipt	If this record represents a supply from a ScheduledReceipt, then this field is a reference to that ScheduledReceipt. If this record represents a demand that is an allocation from a ScheduledReceipt, then this field is a reference to that ScheduledReceipt. In all other situations, this field is NULL. **Referenced table:** ScheduledReceipt	Reference	
ShipDate	The date the supply should be shipped from its supplier to meet ReschedDate. Copied from PlannedOrder or ScheduledReceipt. D'undefined' for other types of Activity records.	Date	
StartUnit	The start unit that is applicable to this supply or demand. The field is populated from the source supply or demand record regardless of the value for Part.MUEPoolNettingType.UnitRule.	Integer	
StockUnit Quantity	Represents the supply quantity in inventory unit of measure (UOM) without applying yield or scrap factors. **Note**: **SupplierUOM** applies to **StockUnitQuantity**.	Quantity	

Table 8.22: CTPActivity (Mfg) fields

Field name	Description	Data type	Owner
Supplier	Reference to the name of the supplier. The supplier of the part. NULL if the supply is from on hand, or if the activity is a demand. **Referenced table:** Supplier	Reference	
SupplyQty	For supplies, the total quantity of the supply (DemandQty will be the received quantity). For demands, the quantity that has been satisfied (shipped or consumed forecast). If the ExtendedType field is set to "Expiring", then this field is always set to zero (0).	Quantity	
SupplyQtyUnitOfMeasure	Reference to the unit of measure used for the supply quantity that is associated with this record. **Referenced table:**"UnitOfMeasure table" on page 931. **Note**: This field was added in Version 2016.2, Service Update 12.	Reference	
SupplyType	The SupplyType associated with this record.	String	
Synchronized Date	This field synchronizes the consumption of components based on the parent supply. In some inventory calculations, usage of this date is therefore more appropriate than **DueDate**. Calculated as follows: • For dependent demands, this is the date where the demand is required and expected to be consumed, based on the converting the parent supply's **FirstAvailableDate** to a **StartDate**. • For independent demands and unconsumed forecast, this is the demand AvailableDate. • For supplies, it is the **AvailableDate**.	Date	
Transaction Sequence	Sequence from supply or demand. 0 if not relevant or no corresponding Transaction Sequence field in the originating table.	Integer	

Table 8.22: CTPActivity (Mfg) fields

Field name	Description	Data type	Owner
Type	Identifies the type of activity record. Values are: • Allocation • AvailableToPromise (not used) • CoByProductSupply • ConsensusForecast • DynamicSafety (not used) • Forecast • IndependentDemand • InventoryTransfer • InventoryTransferAllocation • NewAllocation • NewTransferAllocation • OnHand • PlannedAllocation • PlannedOrder • PlannedTransferAllocation • PushTransferOut—Indicates that this demand transaction is an action indicating that the quantity should be pushed out early to the destination site in order to respect the maximum inventory level. This type applies only to source parts that are enabled for push planning (have **DistributionPlanningRule.ProcessingRule** set to "Enable". If those parts also have **DistributionPlanningRule.SupplyShareRule** set to "All", then this type will be found on all actions representing transfers from the source site to destination site. **Note:** This value was added in Version 2016.2. • ScheduledReceipt • SubstituteSupply • SubstituteAllocation	String (Enum)	

CTPCoByProductSupply table

The CTPCoByProductSupply table reports capable-to-promise calculations, such as available dates and on time quantities, for co-product and by-product supplies. Co-products are those that are manufactured together with a primary product and typically have similar components and process similarities as the primary product. By-products are those that are generated as a result of, and residual to, production of the primary product.

Table 8.23: CTPCoByProductSupply (Mfg) fields

Field name	Description	Data type	Owner
AvailableDate	The date when this supply will be available. This is calculated starting from the available date of the primary product supply that generated this co-product or by-product, and then adjusted by the **BillOfMaterial.LeadTimeOffset** value, if any, in the record that defines this co-product or by-product relationship.	Date	
CoByProduct Supply	A reference to the CoByProductSupply record that is associated with this CTP record. **Referenced table:** CoByProductSupply	Reference	
Expiring Quantity	The amount of this supply that will not be used before it expires (reaches its ExpiryDate and is no longer usable).	Quantity	
ExpiryDate	The date when this supply will expire. This is calculated starting from the expiry date of the primary product supply that generated this co-product or by-product, and then adjusted by some number of the primary products expiry calendar intervals. This adjustment, if any, is made in terms of the **BillOfMaterial.IntervalToExpiryOffset** value in the record that defines this co-product or by-product relationship.	Date	
ExpiryStart Date	Date on which to start supply expiry date calculations for assemblies having a **PartType.ExpiryRule** of "DependentStart" (based on earliest ExpiryStartDate rolled up from a component supply). This field is calculated for all expiring primary parts that are either designated as limiting components or contain limiting components in their product structure. Otherwise, this field is set to "Future". For more information about how supply expiry start dates are used, see "DependentStart" on page 1618.	Date	
FirstAvailable Date	If incremental availability is turned on for the part, this represents the date the first portion of the supply could be available. If incremental availability is turned off for the part, this is always the same as AvailableDate.	Date	
NewProcess Cost	Standard labor and overhead cost to complete this supply. Cost values used in this calculation are taken from the part source used in production of the primary product supply that generated this co-product or by-product. Cost is calculated by the percentage associated with this co-product or by-product in relation to the primary product. Currency conversions on this field use the **DueDate** field's conversion rate.	Money	

Table 8.23: CTPCoByProductSupply (Mfg) fields

Field name	Description	Data type	Owner
NewPurchase Cost	Cost of new purchases to complete this supply. Cost values used in this calculation are taken from the part source used in production of the primary product supply that generated this co-product or by-product. Cost is calculated by the percentage associated with this co-product or by-product in relation to the primary product. Currency conversions on this field use the **DueDate** field's conversion rate.	Money	
OnTime Quantity	The amount of this supply that will be available by its due date.	Quantity	
Part	A reference to the co-product or by-product part that this supply is for. **Referenced table:** Part	Reference	Yes
PrimaryPart	A reference to the primary product whose planned order or scheduled receipt generated this co-product or by-product supply. **Referenced table**: Part	Reference	
PrimaryCTP PlannedOrder	A reference to the CTPPlannedOrder record associated with the primary product's planned order that generated this co-product or by-product. Null if the primary product supply is a scheduled receipt. **Referenced table:** CTPPlannedOrder	Reference	
Primary Scheduled Receipt	A reference to the primary product's scheduled receipt that generated this co-product or by-product. Null if the primary product supply is a planned order. **Referenced table:** ScheduledReceipt	Reference	

CTPForecast table

The **CTPForecast** table reports capable-to-promise calculations, such as available dates and on time quantities, pertaining to forecasted demands generated during the sales and operations planning process in RapidResponse. That is, this table only contains availability details of forecasts based on values in the **ForecastDetail** table and used in generating the consensus forecast (as reported in the **ConsensusForecast** table and in **Forecast** table records with a ForecastSource value of "ConsensusForecast").

This table is not shown on the *RapidResponse Calculated Data Model* poster.

Table 8.24: CTPForecast (Mfg) fields

Field name	Description	Data type	Owner
AvailableDate	The date at which supply is available to fully satisfy this forecasted demand.	Date	
DaysLate	The number of days late (in working days) this demand is expected to be.	Quantity	
Forecast	A reference to the forecast whose availability is reported in this record. Only Forecast records with a ForecastSource value of "ConsensusForecast" are referenced from this table. **Referenced table:** Forecast	Reference	
OnTime Quantity	The amount of this demand which can be satisfied on time.	Quantity	
Part	A reference to the part this forecast is for. **Referenced table:** Part	Reference	Yes

CTPForecastCost table

The **CTPForecastCost** table reports date-based cost of goods sold and material spending values for forecasts generated by the S&OP process in RapidResponse (that is, those forecasts whose details are reported in the **CTPForecast** tables). For a given forecast, this table contains one record for each date on which any component supplies pegged to the forecast in the **WhereConsumedForForecast** table are due.

This table is not shown on the *RapidResponse Calculated Data Model* poster. It is meant to replace the now obsolete **CostOfGoodsSoldForForecast** table which generated only one summary record per forecast. As a result, in cases where component supplies due on different dates were required to satisfy a given forecast, the **CostOfGoodsSoldForForecast** table would potentially give incorrect results if used in multi-currency environments.

Table 8.25: CTPForecastCost (Mfg) fields

Field name	Description	Data type	Owner
ConversionDate	The particular date to which the cost values reported on this record apply. Each forecast has one record added this table for each unique date on which one or more required component supplies are due based on the results in the **WhereConsumedForForecast** table. This date then becomes effective date for any related currency conversion calculations to ensure the appropriate date-sensitive rates are used.	Date	
CostOfGoods Sold	The total costs of goods sold from all component supplies due on this date and used in satisfying the referenced forecast. For a given date and set of component supplies pegged to this forecast in the **WhereConsumedForForecast** table, the **LaborCost**, **MaterialCost**, **OverheadCost**, and **OverheadCost2** fields are summed together to populate this field.	Money	
CTPForecast	A reference to the capable-to-promise details for the forecasted demand whose cost of goods sold and associated material spending is reported in this record. Details of the **Forecast** record itself can also be accessed through this reference. **Referenced table:** CTPForecast	Reference	
MaterialSpend	Total rolled-up material spending associated with component supplies due on this date and used in satisfying the referenced forecast. For any scheduled receipts or planned orders for purchased parts that are pegged to this demand in the **WhereConsumedForForecast** table, the **MaterialCost** field values are summed together to populate this field.	Money	
Part	A reference to the part associated with the forecasted demand whose cost of goods sold and associated material spending is reported in this record. **Referenced table**: Part	Reference	Yes

CTPPlannedOrder table

This table stores capable-to-promise information for planned orders based on things such as component and constraint availability. For example, you can determine if a supply is late due to lack of constraint or component materials by comparing the value of the MaterialAvailableDate field with the value of the AvailableDate field.

Table 8.26: CTPPlannedOrder (Mfg) fields

Field name	Description	Data type	Owner
AvailableDate	The date this supply could be available based on materials, Constraint, and due date.	Date	
AvailableStart Date	The Start date calculated from earliest constraint allocation. If the incremental availability option is turned off for the supply, then all components must be available before any constraint be allocated. If the incremental availability option is turned on for the supply then only some set of components need be available before any constraint can be allocated. **NOTE**: If there is no active constraint, this date is calculated from AvailableDate. **NOTE**: If fixed constraint is required (**SourceConstraint.FixedConstraintFactor > 0**) and the amount of that fixed requirement exceeds the total constraint immediately available, then this date can end up being later than the earliest constraint allocation. In such situations, the total fixed constraint required might need to collected over several days/periods before the supply can start.	Date	
Constraint	The Constraint whose insufficient remaining capacity will make the entire supply not available for its MaterialAvailableDate. If this supply is not late, this field is empty. **Referenced table:** Constraint	Reference	
Expiring Quantity	The amount of this supply that will not be used before it expires (reaches its ExpiryDate).	Date	
ExpiryDate	The date on which the material in this supply expires (is no longer usable).	Date	
ExpiryStartDate	Calculated date on which to start supply expiry date calculations for assemblies having a **PartType.ExpiryRule** of "DependentStart". This field is calculated for all expiring parts that are either designated as limiting components or contain limiting components in their product structure. Otherwise, this field is set to "Future". For more information about how supply expiry start dates are used, see "DependentStart" on page 1618.	Date	
FirstAvailable Date	The date the first portion of this supply is available. This is different than the AvailableDate field in cases where the planned order has been split into multiple periods due to constraint consumption or incremental availability of component materials.	Date	

Table 8.26: CTPPlannedOrder (Mfg) fields

Field name	Description	Data type	Owner
Material Available Date	Date when all materials are available (MaterialStartDate) converted to a Stock date.	Date	
MaterialStart Date	Date when all components are available for the entire supply. For work orders, this is based on component availability. For purchase orders, this is the same as StartDate.	Date	
NewProcess Cost	Standard labor and overhead cost of planned orders to complete this order. Labor and overhead costs values are taken from the applicable **PartSource** records or, the applicable **TimePhasedPartSourceAttributes** records (if they exist). Currency conversions on this field use the **DueDate** field's conversion rate.	Money	
NewPurchases Cost	Cost of new purchases required in order to complete this order (through all levels of the bill). Note that fields used to calculate the various purchase values for supplies is determined by the setting in the **PartSourceType.CostRule** field. Currency conversions on this field use the **DueDate** field's conversion rate.	Money	
OnTime Quantity	The quantity of the entire planned order that could be available for DueDate, based on lead time and component availability only.	Quantity	
Part	The part this record relates to. **Referenced table:** Part	Reference	Yes
PlannedOrder	The planned order applicable to this record. **Referenced table:** PlannedOrder	Reference	

CTPSafetyStockHoldings table

The **CTPSafetyStockHoldings** table reports details of supply allotments that are available to support safety stock levels. For example, allotments of supply that have been temporarily held from their demands in order to ensure minimum safety stock levels are not violated (or are minimally violated if doing so cannot be avoided).

This table was added in Version 2016.2, Service Update 18. It is only populated for parts' where **SafetyStockPolicy.CTPHoldRule** is set to "Use" (where supply allotments can be temporarily held from their demands in order to protect higher priority safety stock requirements). For more information about held allotments and prioritized safety stock, see "Priority and safety stock holds in CTP" on page 1780.

Table 8.27: CTPSafetyStockHoldings(Mfg) fields

Field name	Description	Data type	Owner
Date	A date on which there is a supply allotment available towards maintaining the safety stock level. Records are generated on dates on which there is a change in the quantity of supply allotments available to support the safety stock level, as well as dates on which there is a change in the specific supply allotments that support a given safety stock level.	Date	
OrderPriority	The priority of the safety stock requirement for which the supply allotment was held. This is either the **OrderPriority** referenced on a **TimePhasedSafety** record for the part, or else the part's **PartType.DefaultPriority**. Note that this will always be a higher priority than that found on any actual demand whose allotment is held to respect the safety stock requirement. **Referenced table**: OrderPriority	Reference	
Part	The part with a supply allotment that has been held. **Referenced table**: Part	Reference	Yes
SupplyDemand	A reference to a **SupplyDemand** allotment that supports safety stock. The following types of allotments will be reported: • supply allotments made to actual demands which are then held to avoid violating a higher priority safety stock requirement. Held allotments are available between **HoldStartDate** and **HoldEndDate**. • supply that is being pushed (transferred) from a sourcing location to a distribution site in respect of the part's maximum inventory level. Pushed allotments are available between **SupplyAvailableDate** and **PushDate**. • supply allotments made to actually satisfy a safety stock requirement (records where **DemandSource** is set to "None"). **Referenced table**: SupplyDemand	Reference	

Note: A worksheet based on this table that grouped by **Part** and **Date** (and optionally **OrderPriority**), and then summed by the referenced **SupplyDemand.AllocatedQty** values, can show all supply available to support safety stock as of a given date.

CTPSubstituteSupply table

The **CTPSubstituteSupply** table shows the results of capable-to-promise calculations where supply of a substitute part was used to satisfy demand for a primary part.

Note that this table shows the results of global part substitute calculations only (it does not consider BOM-level part substitution).

Table 8.28: CTPSubstituteSupply (Mfg) fields

Field name	Description	Data type	Owner
AvailableDate	The date this supply should be available.	Date	
ExpiringQuantity	The amount of this supply that will not be used before its expiry date.	Date	
ExpiryDate	The date that this supply will expire.	Date	
ExpiryStartDate	Date on which to start supply expiry date calculations for assemblies having a **PartType.ExpiryRule** of "DependentStart" (based on earliest ExpiryStartDate rolled up from a component supply). This field is calculated for all expiring substitute parts that are either designated as limiting components or contain limiting components in their product structure. Otherwise, this field is set to "Future". For more information about how supply expiry start dates are used, see "DependentStart" on page 1618.	Date	
FirstAvailableDate	If incremental availability is turned on for the part, this represents the date the first portion of the supply could be available. If incremental availability is turned off for the part, this is the same as AvailableDate.	Date	
NewProcessCost	Standard labor and overhead cost rolled up from lower levels. Currency conversions on this field use the **DueDate** field's conversion rate.	Money	
NewPurchaseCost	New purchase costs rolled up from lower levels. Currency conversions on this field use the **DueDate** field's conversion rate.	Money	
OnTimeQuantity	The amount of the supply that could be available for the DueDate (based on component availability only).	Quantity	
Part	The primary part that needed supply from a substitute part. **Referenced table:** Part	Reference	Yes
SubstituteSupply	A reference to the related substitute supply record which provides more details on the supply and the primary part's demand it satisfies. **Referenced table:** SubstituteSupply	Reference	

DataChange table

This table is used to track user-initiated data changes between a scenario and its parent. It indicates changes made to data in a given scenario as well as changes made in its parent that the scenario has not yet been updated with.

The following types of changes are recorded in this table:

- **Insert**—for each record insertion in a scenario, a single record is added to this table. If an inserted record is subsequently modified, the insert record is updated with the new values and no modification record is created (as long as there have been no intervening scenario operations involving that scenario).
- **Modify**—for each individual field value modified on a given record in a scenario, a single record is added to this table. If a single user makes multiple modifications to a given field value in a scenario, only one modification record is created (as long as there have been no intervening scenario operations involving that scenario).
- **Delete**—for each record deletion in a scenario, a single record is added to this table. When a record is deleted, any existing data change records pertaining to it (inserts or modifications) are also deleted. As well, any deletions that happen as a result of another deletion are not recorded.

Note: User-initiated changes do not include adhoc data imports, data updates to a specific scenario, and automatic data modifications.

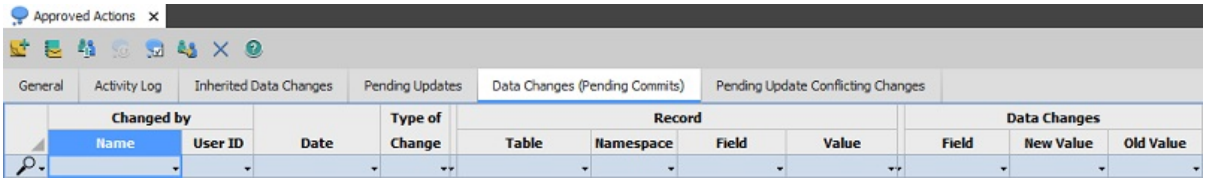
The DataChange table is used in the Changes to Root Scenario worksheet in the Administration Log workbook.

Changes to Root Scenario worksheet

RapidResponse 2016.2 introduced three tables that are almost identical to the DataChange table. Each of these tables run faster than the original DataChange table and are less memory intensive. The three tables each support a worksheet in the Scenario properties window.

- **Inherited Data Changes** tab (DataChange_Historical table)
- **Pending Updates** tab (DataChange_PendingUpdate table)
- **Data Changes (Pending Commits)** tab (DataChange_Local table)

Figure 8.1 Scenario properties - Data Changes (Pending Commits)



Using the DataChange tables and worksheets can help users better understand differences between a parent scenario and a child scenario. For example, suppose you are ready to commit data changes to a parent scenario. For each scenario in your Scenarios pane, the changes in the scenario can be viewed along with details of each change, such as the user who made the change, the type of action that resulted in the change, and the field values affected by the change. These changes are viewed through the Data Changes (Pending Commits) worksheet in the Scenario Properties tab.

Notes:

- For fields in this table containing delimited lists of values, the pipe character (|) is used to separate the values. If necessary, the delimiter character can be changed. Typically, this would be done if the delimiter character is used in your data set. For more information, see "Configuring data change tracking" in the *RapidResponse Administration Guide*.
- RapidResponse automatically logs information about data change records in the DataChange table. Over time, these records can grow in size and potentially consume significant amounts of memory. By default, RapidResponse automatically deletes data change records after 45 days. However, the frequency in which these records are deleted can be configured by an administrator. For more information, see the *RapidResponse Administration Guide*.
- A data import deletes all existing data change records.

Table 8.29: DataChange fields

Field name	Description	Data	Owner
ChangeDate Time	The date and time when the change to the scenario was made.	DateTime	
ChangedField Names	Delimited list of the fields affected by this change. The field names that display depend on the type of change as follows: • **Insert**—a delimited list of the field names from the record that is added. Usually a subset of all the field names on the record. • **Modify**—a delimited list of the names of the fields that have changed. • **Delete**—this field is blank.	String	
ChangedField Schema	Schema of value fields for changes made against referenced tables.	String	
ChangedField Values	Delimited list of the new values that now exist in the fields identified in **ChangedFieldNames**.	String	
ChangeRecord Handle	Record handle of the internal change record in RapidResponse.	Integer	
Comment	This field is reserved for future use in RapidResponse.	String	

Table 8.29: DataChange fields

Field name	Description	Data	Owner
DataChange Source	Indicates the source of this change (for example, is the change in this scenario or its parent). Valid values are: • **Historical**—A change that previously occurred in a parent of this scenario, and was inherited by this scenario when it was derived from its parent. • **Local**—A change that occurred in this scenario (or was committed into this scenario). • **PendingUpdate**—A change made in the parent scenario, that has not yet been updated into this scenario.	String (Enum)	
Identification FieldNames	A delimited list of fields from the table where the change occurred, that are used to identify the record that has changed. In a typical case, these are the fields which make up a table's primary key. An administrator can also define the fields used to identify records as discussed in "Configuring data change tracking" in the *RapidResponse Administration Guide*.	String	
Identification FieldValues	A delimited list of values from the table where the change occurred and used to identify the record that has changed. These values correspond to the fields listed in **IdentificationFieldNames**.	String	
Origin	Always returns the value **User**. This field is maintained for compatibility purposes and can be ignored.	String (Enum)	
OriginalField Values	For changes of the type **Modify**, a delimited list of the original values from the changed fields (that is, those fields listed in **ChangedFieldNames**).	String	
ScenarioPath	The name of the scenario where the changes have occurred. The notation of the scenario is based on the full path from the root scenario. The path levels are noted using **/~/**. For example, the full path for the Child scenario of Enterprise Data is noted as `/~/Enterprise Data/~/Child/~/`.	String	
Sequence	When combined with **ChangeDateTime**, ensures that all changes resulting from a single user action can be grouped together. For example, if 10 records are modified as part of a single change action, they are all assigned the same **Sequence** (and **ChangeDateTime** value).	Integer	

Table 8.29: DataChange fields

Field name	Description	Data	Owner
Site	The corresponding site name for the data changes. **Referenced table**: Site	Reference	
SourceRecord Handle	Record handle associated with the record affected by the change (insertions and modifications only).	Integer	
Table	The name of the table where the change was made.	String	
Type	Indicates the type of change that occurred. Valid values are: • **Insert**—a new record was added. • **Modify**—an existing record was changed. • **Delete**—an existing record was deleted	String (Enum)	
User	The User ID of the user who made the change.	String	
UserRecord	A reference to the record that identifies the user who made the change. This is either the same value as User, or it might be NULL if the user has been deleted. **Referenced table**: User	Reference	

DataChange_Historical table

This table is used to track user-initiated data changes between a scenario and its parent. It indicates only those changes that previously occurred in a parent of this scenario, and was inherited by this scenario when it was derived from its parent.

This table is almost identical to the DataChange table except that it runs faster and is less memory intensive since only one type of source of change is reported (Historical). This table supports the Inherited Data Changes worksheet tab in the Scenario properties window.

The following types of changes are recorded in this table:

- **Insert**—for each record insertion in a scenario, a single record is added to this table. If an inserted record is subsequently modified, the insert record is updated with the new values and no modification record is created (as long as there have been no intervening scenario operations involving that scenario).
- **Modify**—for each individual field value modified on a given record in a scenario, a single record is added to this table. If a single user makes multiple modifications to a given field value in a scenario, only one modification record is created (as long as there have been no intervening scenario operations involving that scenario).
- **Delete**—for each record deletion in a scenario, a single record is added to this table. When a record is deleted, any existing data change records pertaining to it (inserts or modifications) are also deleted. As well, any deletions that happen as a result of another deletion are not recorded.

Notes:

- User-initiated changes do not include adhoc data imports, data updates to a specific scenario, and automatic data modifications.
- RapidResponse automatically logs information about data change records in the DataChange table. Over time, these records can grow in size and potentially consume significant amounts of memory. By default, RapidResponse automatically deletes data change records after 45 days. However, the frequency in which these records are deleted can be configured by an administrator. For more information, see the *RapidResponse Administration Guide*.

Table 8.30: DataChange_Historical fields

Field name	Description	Data type	Owner
ChangeDate Time	The date and time when the change to the scenario was made.	DateTime	
ChangedField Names	Delimited list of the fields affected by this change. The field names that display depend on the type of change as follows: • **Insert**—a delimited list of the field names from the record that is added. Usually a subset of all the field names on the record. • **Modify**—a delimited list of the names of the fields that have changed. • **Delete**—this field is blank.	String	
ChangedField Schema	Schema of value fields for changes made against referenced tables.	String	
ChangedField Values	Delimited list of the new values that now exist in the fields identified in **ChangedFieldNames**.	String	
ChangeRecord Handle	Record handle of the internal change record in RapidResponse.	Integer	
Comment	This field is reserved for future use in RapidResponse.	String	
DataChange Source	Indicates the source of this change (for example, is the change in this scenario or its parent). A valid value is: • **Historical**—A change that previously occurred in a parent of this scenario, and was inherited by this scenario when it was derived from its parent.	String (Enum)	

Table 8.30: DataChange_Historical fields

Field name	Description	Data type	Owner
Identification FieldNames	A delimited list of fields from the table where the change occurred, that are used to identify the record that has changed. In a typical case, these are the fields which make up a table's primary key. An administrator can also define the fields used to identify records as discussed in "Configuring data change tracking" in the *RapidResponse Administration Guide*.	String	
Identification FieldValues	A delimited list of values from the table where the change occurred and used to identify the record that has changed. These values correspond to the fields listed in **IdentificationFieldNames**.	String	
Origin	Always returns the value **User**. This field is maintained for compatibility purposes and can be ignored.	String (Enum)	
OriginalField Values	For changes of the type **Modify**, a delimited list of the original values from the changed fields (that is, those fields listed in **ChangedFieldNames**).	String	
ScenarioPath	The name of the scenario where the changes have occurred. The notation of the scenario is based on the full path from the root scenario. The path levels are noted using **/~/**. For example, the full path for the Child scenario of Enterprise Data is noted as `/~/Enterprise Data/~/Child/~/`	String	
Sequence	When combined with **ChangeDateTime**, ensures that all changes resulting from a single user action can be grouped together. For example, if 10 records are modified as part of a single change action, they are all assigned the same **Sequence** (and **ChangeDateTime** value).	Integer	
Site	The corresponding site name for the data changes. **Referenced table**: Site	Reference	
SourceRecord Handle	Record handle associated with the record affected by the change (insertions and modifications only).	Integer	
Table	The name of the table where the change was made.	String	

Table 8.30: DataChange_Historical fields

Field name	Description	Data type	Owner
Type	Indicates the type of change that occurred. Valid values are: • **Insert**—a new record was added. • **Modify**—an existing record was changed. • **Delete**—an existing record was deleted	String (Enum)	
User	The User ID of the user who made the change.	String	
UserRecord	A reference to the record that identifies the user who made the change. This is either the same value as User, or it might be NULL if the user has been deleted. **Referenced table**: User	Reference	

DataChange_Historical_Split table

This table is used to track user-initiated data changes between a scenario and its parent. It indicates only those changes that previously occurred in a parent of this scenario, and was inherited by this scenario when it was derived from its parent.

This table is almost identical to the DataChange_Historical table except that it splits each identifying field and modified field from the DataChange_Historical table into a separate record. This reports the data changes in the Scenario properties window, and does not require an additional processing step to parse the DataChange record values into the worksheet format.

The following types of changes are recorded in this table:

- **Insert**—for each record insertion in a scenario, a single record is added to this table. If an inserted record is subsequently modified, the insert record is updated with the new values and no modification record is created (as long as there have been no intervening scenario operations involving that scenario).
- **Modify**—for each individual field value modified on a given record in a scenario, a single record is added to this table. If a single user makes multiple modifications to a given field value in a scenario, only one modification record is created (as long as there have been no intervening scenario operations involving that scenario).
- **Delete**—for each record deletion in a scenario, a single record is added to this table. When a record is deleted, any existing data change records pertaining to it (inserts or modifications) are also deleted. As well, any deletions that happen as a result of another deletion are not recorded.

Notes:

- User-initiated changes do not include adhoc data imports, data updates to a specific scenario, and automatic data modifications.
- RapidResponse automatically logs information about data change records in the DataChange table. Over time, these records can grow in size and potentially consume significant amounts of memory. By default, RapidResponse automatically deletes data

change records after 45 days. However, the frequency in which these records are deleted can be configured by an administrator. For more information, see the *RapidResponse Administration Guide*.

Table 8.31: DataChange_Historical_Split fields

Field name	Description	Data type	Owner
ChangeDate Time	The date and time when the change to the scenario was made.	DateTime	
ChangedField Names	Delimited list of the fields affected by this change. The field names that display depend on the type of change as follows: • **Insert**—a delimited list of the field names from the record that is added. Usually a subset of all the field names on the record. • **Modify**—a delimited list of the names of the fields that have changed. • **Delete**—this field is blank.	String	
ChangedField Schema	Schema of value fields for changes made against referenced tables.	String	
ChangedField Values	Delimited list of the new values that now exist in the fields identified in **ChangedFieldNames**.	String	
ChangeRecord Handle	Record handle of the internal change record in RapidResponse.	Integer	
Comment	This field is reserved for future use in RapidResponse.	String	
DataChange Source	Indicates the source of this change (for example, is the change in this scenario or its parent). A valid value is: • **Historical**—A change that previously occurred in a parent of this scenario, and was inherited by this scenario when it was derived from its parent.	String (Enum)	
Identification FieldNames	A delimited list of fields from the table where the change occurred, that are used to identify the record that has changed. In a typical case, these are the fields which make up a table's primary key. An administrator can also define the fields used to identify records as discussed in "Configuring data change tracking" in the *RapidResponse Administration Guide*.	String	

Table 8.31: DataChange_Historical_Split fields

Field name	Description	Data type	Owner
Identification FieldValues	A delimited list of values from the table where the change occurred and used to identify the record that has changed. These values correspond to the fields listed in **IdentificationFieldNames**.	String	
Origin	Always returns the value **User**. This field is maintained for compatibility purposes and can be ignored.	String (Enum)	
OriginalField Values	For changes of the type **Modify**, a delimited list of the original values from the changed fields (that is, those fields listed in **ChangedFieldNames**).	String	
Line	The line number of the record split from the DataChange_ Historical table.	Integer	
ScenarioPath	The name of the scenario where the changes have occurred. The notation of the scenario is based on the full path from the root scenario. The path levels are noted using **/~/**. For example, the full path for the Child scenario of Enterprise Data is noted as `/~/Enterprise Data/~/Child/~/`	String	
Sequence	When combined with **ChangeDateTime**, ensures that all changes resulting from a single user action can be grouped together. For example, if 10 records are modified as part of a single change action, they are all assigned the same **Sequence** (and **ChangeDateTime** value).	Integer	
Site	The corresponding site name for the data changes. **Referenced table**: Site	Reference	
SourceRecord Handle	Record handle associated with the record affected by the change (insertions and modifications only).	Integer	
SplitGroupSequence	The sequence number assigned to each data change. All lines for a single change are assigned the same group sequence number, and the group represents a single row from the DataChange_PendingUpdate table.	Integer	
Table	The name of the table where the change was made.	String	

Table 8.31: DataChange_Historical_Split fields

Field name	Description	Data type	Owner
Type	Indicates the type of change that occurred. Valid values are: • **Insert**—a new record was added. • **Modify**—an existing record was changed. • **Delete**—an existing record was deleted	String (Enum)	
User	The User ID of the user who made the change.	String	
UserRecord	A reference to the record that identifies the user who made the change. This is either the same value as User, or it might be NULL if the user has been deleted. **Referenced table**: User	Reference	

DataChange_Local table

This table is used to track user-initiated data changes between a scenario and its parent. It indicates a change that occurred only in this scenario (or was committed into this scenario).

This table is almost identical to the DataChange table except that it runs faster and is less memory intensive since only one type of source of change is reported (Local). This table supports the Data Changes (Pending Commits) worksheet tab in the Scenario properties window.

The following types of changes are recorded in this table:

- **Insert**—for each record insertion in a scenario, a single record is added to this table. If an inserted record is subsequently modified, the insert record is updated with the new values and no modification record is created (as long as there have been no intervening scenario operations involving that scenario).
- **Modify**—for each individual field value modified on a given record in a scenario, a single record is added to this table. If a single user makes multiple modifications to a given field value in a scenario, only one modification record is created (as long as there have been no intervening scenario operations involving that scenario).
- **Delete**—for each record deletion in a scenario, a single record is added to this table. When a record is deleted, any existing data change records pertaining to it (inserts or modifications) are also deleted. As well, any deletions that happen as a result of another deletion are not recorded.

Notes:

- User-initiated changes do not include adhoc data imports, data updates to a specific scenario, and automatic data modifications.
- RapidResponse automatically logs information about data change records in the DataChange table. Over time, these records can grow in size and potentially consume significant amounts of memory. By default, RapidResponse automatically deletes data change records after 45 days. However, the frequency in which these records are deleted can

be configured by an administrator. For more information, see the *RapidResponse Administration Guide*.

Table 8.32: DataChange_Local fields

Field name	Description	Data	Owner
ChangeDateTime	The date and time when the change to the scenario was made.	DateTime	
ChangedField Names	Delimited list of the fields affected by this change. The field names that display depend on the type of change as follows: • **Insert**—a delimited list of the field names from the record that is added. Usually a subset of all the field names on the record. • **Modify**—a delimited list of the names of the fields that have changed. • **Delete**—this field is blank.	String	
ChangedField Schema	Schema of value fields for changes made against referenced tables.	String	
ChangedField Values	Delimited list of the new values that now exist in the fields identified in **ChangedFieldNames**.	String	
ChangeRecord Handle	Record handle of the internal change record in RapidResponse.	Integer	
Comment	This field is reserved for future use in RapidResponse.	String	
DataChangeSource	Indicates the source of this change (for example, is the change in this scenario or its parent). A valid value is: • **Local**—A change that occurred in this scenario (or was committed into this scenario).	String (Enum)	
IdentificationField Names	A delimited list of fields from the table where the change occurred, that are used to identify the record that has changed. In a typical case, these are the fields which make up a table's primary key. An administrator can also define the fields used to identify records as discussed in "Configuring data change tracking" in the *RapidResponse Administration Guide*.	String	
IdentificationField Values	A delimited list of values from the table where the change occurred and used to identify the record that has changed. These values correspond to the fields listed in **IdentificationFieldNames**.	String	

Table 8.32: DataChange_Local fields

Field name	Description	Data	Owner
Origin	Always returns the value **User**. This field is maintained for compatibility purposes and can be ignored.	String (Enum)	
OriginalFieldValues	For changes of the type **Modify**, a delimited list of the original values from the changed fields (that is, those fields listed in **ChangedFieldNames**).	String	
ScenarioPath	The name of the scenario where the changes have occurred. The notation of the scenario is based on the full path from the root scenario. The path levels are noted using **/~/**. For example, the full path for the Child scenario of Enterprise Data is noted as `/~/Enterprise Data/~/Child/~/`	String	
Sequence	When combined with **ChangeDateTime**, ensures that all changes resulting from a single user action can be grouped together. For example, if 10 records are modified as part of a single change action, they are all assigned the same **Sequence** (and **ChangeDateTime** value).	Integer	
Site	The corresponding site name for the data changes. **Referenced table**: Site	Reference	
SourceRecord Handle	Record handle associated with the record affected by the change (insertions and modifications only).	Integer	
Table	The name of the table where the change was made.	String	
Type	Indicates the type of change that occurred. Valid values are: • **Insert**—a new record was added. • **Modify**—an existing record was changed. • **Delete**—an existing record was deleted	String (Enum)	
User	The User ID of the user who made the change.	String	
UserRecord	A reference to the record that identifies the user who made the change. This is either the same value as User, or it might be NULL if the user has been deleted. **Referenced table**: User	Reference	

DataChange_Local_Split table

This table is used to track user-initiated data changes between a scenario and its parent. It indicates a change that occurred only in this scenario (or was committed into this scenario).

This table is almost identical to the DataChange_Local table except that it splits each identifying field and modified field from the DataChange_Local table into a separate record. This reports the data changes in the Scenario properties window, and does not require an additional processing step to parse the DataChange record values into the worksheet format.

The following types of changes are recorded in this table:

- **Insert**—for each record insertion in a scenario, a single record is added to this table. If an inserted record is subsequently modified, the insert record is updated with the new values and no modification record is created (as long as there have been no intervening scenario operations involving that scenario).
- **Modify**—for each individual field value modified on a given record in a scenario, a single record is added to this table. If a single user makes multiple modifications to a given field value in a scenario, only one modification record is created (as long as there have been no intervening scenario operations involving that scenario).
- **Delete**—for each record deletion in a scenario, a single record is added to this table. When a record is deleted, any existing data change records pertaining to it (inserts or modifications) are also deleted. As well, any deletions that happen as a result of another deletion are not recorded.

Notes:

- User-initiated changes do not include adhoc data imports, data updates to a specific scenario, and automatic data modifications.
- RapidResponse automatically logs information about data change records in the DataChange table. Over time, these records can grow in size and potentially consume significant amounts of memory. By default, RapidResponse automatically deletes data change records after 45 days. However, the frequency in which these records are deleted can be configured by an administrator. User	The User ID of the user who made the change.	String	
UserRecord	A reference to the record that identifies the user who made the change. This is either the same value as User, or it might be NULL if the user has been deleted. **Referenced table**: User	Reference	

DataChange_PendingUpdate table

This table is used to track user-initiated data changes between a scenario and its parent. It indicates only those changes made in the parent scenario, that have not yet been updated into this scenario.

This table is almost identical to the DataChange table except that it runs faster and is less memory intensive since only one type of source of change is reported (PendingUpdate). This table supports the Pending Updates worksheet tab in the Scenario properties window.

The following types of changes are recorded in this table:

- **Insert**—for each record insertion in a scenario, a single record is added to this table. If an inserted record is subsequently modified, the insert record is updated with the new values and no

modification record is created (as long as there have been no intervening scenario operations involving that scenario).

- **Modify**—for each individual field value modified on a given record in a scenario, a single record is added to this table. If a single user makes multiple modifications to a given field value in a scenario, only one modification record is created (as long as there have been no intervening scenario operations involving that scenario).
- **Delete**—for each record deletion in a scenario, a single record is added to this table. When a record is deleted, any existing data change records pertaining to it (inserts or modifications) are also deleted. As well, any deletions that happen as a result of another deletion are not recorded.

Notes:

- User-initiated changes do not include adhoc data imports, data updates to a specific scenario, and automatic data modifications.
- RapidResponse automatically logs information about data change records in the DataChange table. Over time, these records can grow in size and potentially consume significant amounts of memory. By default, RapidResponse automatically deletes data change records after 45 days. However, the frequency in which these records are deleted can be configured by an administrator. For more information, see the *RapidResponse Administration Guide*.

Origin	Always returns the value **User**. This field is maintained for compatibility purposes and can be ignored.	String (Enum)	
OriginalFieldValues	For changes of the type **Modify**, a delimited list of the original values from the changed fields (that is, those fields listed in **ChangedFieldNames**).	String	
Line	The line number of the record split from the DataChange_ PendingUpdate table.	Integer	
ScenarioPath	The name of the scenario where the changes have occurred. The notation of the scenario is based on the full path from the root scenario. The path levels are noted using **/~/**. For example, the full path for the Child scenario of Enterprise Data is noted as `/~/Enterprise Data/~/Child/~/`	String	
Sequence	When combined with **ChangeDateTime**, ensures that all changes resulting from a single user action can be grouped together. For example, if 10 records are modified as part of a single change action, they are all assigned the same **Sequence** (and **ChangeDateTime** value).	Integer	
Site	The corresponding site name for the data changes. **Referenced table**: Site	Reference	
SourceRecord Handle	Record handle associated with the record affected by the change (insertions and modifications only).	Integer	
SplitGroupSequence	The sequence number assigned to each data change. All lines for a single change are assigned the same group sequence number, and the group represents a single row from the DataChange_PendingUpdate table.	Integer	
Table	The name of the table where the change was made.	String	

Table 8.35: DataChange_PendingUpdate fields

Field name	Description	Data	Owner
Type	Indicates the type of change that occurred. Valid values are: • **Insert**—a new record was added. • **Modify**—an existing record was changed. • **Delete**—an existing record was deleted	String (Enum)	
User	The User ID of the user who made the change.	String	
UserRecord	A reference to the record that identifies the user who made the change. This is either the same value as User, or it might be NULL if the user has been deleted. **Referenced table**: User	Reference	

Demand table

The **Demand** table is a consolidation table that combines Allocation, IndependentDemand and DependentDemand together for a total demand picture for a part. There is one record for each demand schedule (quantity and due date) per given demand order (planned or firm). This table includes only those demands that are processed by Netting calculations (that is, it excludes demands where date Date is 'Undefined', or where OrderType.ProcessingRule is 'Ignore').

The **Demand** table also reports forecast. The interpretation of TotalQuantity and RemainingQuantity are extended to include forecast, after spreading.

Table 8.36: Demand (Mfg) fields

Field name	Description	Data type	Owner
AlternatePart	The part the demand activity was created for. This value is different from the Part field value only if that part is interchangeable or globally substitutable with this part as follows: • If the part belongs to a set of interchangeable parts, then Part is the primary part and AlternatePart is the part for the input demand data (or for dependent demands, this is where the demand came from). • If the part belongs to a set of globally substitutable parts, then Part is the part that needed the supply and AlternatePart is the part where the demand came from. **Referenced table**: Part	Reference	
DueDate	The date on which the demand is scheduled to be satisfied.	Date	

Table 8.36: Demand (Mfg) fields

Field name	Description	Data type	Owner
EarliestExpiry Date	The earliest date that a supply may expire if it is to be used in satisfying this demand.	Date	
Forecast	A reference to the Forecast record associated with this demand. NULL unless the demand comes from a forecast. **Referenced table:** Forecast	Reference	
Independent Demand	Reference to the IndependentDemand order, NULL if Demand is not an IndependentDemand. **Referenced table:** IndependentDemand	Reference	
IsDependent	Valid values are: • Y • N If 'Y', demand is a dependent demand, 'N' if it is an IndependentDemand or ConsensusForecast.	Boolean	
Inventory Transfer	The Inventory Transfer that is the source of this demand. **Referenced table:** InventoryTransfer	Reference	
Model	The model used when netting this record. **Referenced table:** Model	Reference	
Order	The supply order number Id if this is an Allocation. The demand order number Id if this is an IndependentDemand. Blank if it is a PlannedAllocation.	String	
Part	The part that has the demand. **Referenced table:** Part	Reference	Yes
PegModel	The model that is applicable to this demand. The field is copied from the demand being reported regardless of the value for Part.MUEPoolNettingType.ModelRule. **Referenced table:** Model	Reference	
PegPart	If the demand is dependent demand (for example, IsDependent= 'Y'), PegPart is the assembly being made by the planned order or scheduled receipt. If the demand is from independent demand or from forecast, PegPart is NULL **Referenced table:** Part	Reference	

Table 8.36: Demand (Mfg) fields

Field name	Description	Data type	Owner
PegPool	The pool that is applicable to this demand. This field is copied from the demand being reported regardless of the value for Part.MUEPoolNettingType.PoolRule. **Referenced table:** Pool	Reference	
PegSR	Reference to the ScheduledReceipt if this is an allocation, NULL if otherwise. **Referenced table:** ScheduledReceipt	Reference	
Pool	The pool used when netting this record. **Referenced table:** Pool	Reference	
PromisedDate	The date the part was promised to be available to (DueDate for dependent demands).	Date	
Remaining Quantity	The amount that is still needed. If the Demand is Forecast, this field shows the unconsumed portion of the forecast after spreading.	Quantity	
ReschedDate	The Date MRP moved the DueDate to (may be different from DueDate on dependent demands).	Date	
StartUnit	The start unit that is applicable to this demand. The field is copied from the demand being reported regardless of the value for Part.MUEPoolNettingType.UnitRule.	Integer	
Substitute Supply	The substitute supply that creates the dependent demand **Referenced table:** SubstituteSupply	Reference	
TotalQuantity	The amount that was needed. If the Demand is Forecast, this field shows the total forecast (either dependent or independent) after spreading.	Quantity	
Type	Policies for processing this demand. **Referenced table:** DemandType	Reference	

Table 8.36: Demand (Mfg) fields

Field name	Description	Data type	Owner
UnitSelling Price	The per unit price for this order. If the demand is an independent demand (excluding forecast), then the IndependentDemand.EffectiveUnitPrice is used. For all other demand types (including forecast) the Part.AverageSellingPrice is used. Currency conversions on this field use the **DueDate** field's conversion rate, except in the following case: • If the demand that drives this cost is an inventory transfer, the date from the **ShipDate** field of the InventoryTransfer record is used.	Money	
Unsatisfied Quantity	The portion of this demand that was left unsatisfied.	Quantity	

DemandException table

The **DemandException** table reports demands that were skipped and left unsatisfied either because RapidResponse could not plan supply to meet a part's material expiry requirements, or because the demand date (less safety lead time on the part) fell outside of the effectivity window for all part sources and the part's **SourceRule.DateEffectivityRule** setting was "AdjustedDemandDate", or because multi-level search logic determined that an assembly's components were not expected to be available within the effective date range defined for the assembly's part source(s).

For example, when RapidResponse attempts to generate a planned order to satisfy demand for an expiring part, it does as long as it can find a source where the estimated expiry date for the order is on or after the earliest expiry date for the demand. If it cannot find such a source, the demand is skipped and left unsatisfied. This might occur, for example, if the MinimumShelfLife value defined on the demand/part is greater than the IntervalsToExpiry value defined on the part source.

This table is therefore useful for identifying any demands which were left unsatisfied so that corrective action can subsequently be taken to adjust the supply plan and try to satisfy those demands. For more information about expiry calculations, see "Material expiration" on page 1601. For more information about part source effectivity, see "Part source selection" on page 1377. For more information about multi-level search calculations, see "Multi-level search logic" on page 1863.

Table 8.37: DemandException (Mfg) fields

Field name	Description	Data type	Owner
Constrained ExpiryDate	The latest estimated expiry date associated with any potential planned order that could be sourced from an eligible part source for this part. This date represents the best case scenario for being able to source the demand to meet expiry requirements, but will still be before the EarliestExpiryDate for the demand this exception applies to. This field is left Undefined for exceptions caused by part source effectivity or multi-level source effectivity.	Date	
Date	The date associated with the demand exception for this part. For exceptions caused by material expiry, this typically represents the due date of the demand that was left unsatisfied for the part. For exceptions caused by multi-level part source effectivity, this represents the earliest date that multi-level sourcing logic determined a supply could be planned for the demand (in consideration of component availability and constraint under the assembly). **Note:** The Type field indicates the cause of each demand exception.	Date	
EarliestExpiry Date	The earliest expiry date for the demand that could not be sourced. This represents the date before which any supply cannot expire if it is to be used in satisfying this demand (or demands). This field is left Undefined for exceptions caused by part source effectivity or multi-level source effectivity.	Date	

Table 8.37: DemandException (Mfg) fields

Field name	Description	Data type	Owner
DemandSource	The type of demand that was left unsatisfied due to either material expiry requirements or multi-level source effectivity. This information is useful in helping to track down the demand that was skipped and left unsatisfied. Valid values are: • **Allocation**—input dependent demand from a parent scheduled receipt. • **ConsensusForecast**—consensus forecast demand originating in the ForecastDetail table (other exceptions from forecast are reported under the type of demand they belong to, such as IndependentDemand). • **IndependentDemand**—independent demand for this part (including forecast). • **InventoryTransfer**—inventory transfer from a parent part. • **NewAllocation**—calculated dependent demand from a parent scheduled receipt. • **NewTransferAllocation**—calculated dependent demand from a from a parent transfer scheduled receipt. • **None**—demand to satisfy safety stock. • **OnHand**—demand originating from a negative OnHand record. • **PlannedAllocation**—dependent demand from a parent planned order. • **PlannedTransferAllocation**—dependent demand from a parent transfer planned order. • **SubstituteAllocation**—demand from a substitute allocation.	String (Enum)	
Model	The model, if any, associated with the demand(s) that could not be sourced. **Referenced table:** Model	Reference	
OrderPriority	The order priority associated with the demand(s) that could not be sourced. **Referenced table:** OrderPriority	Reference	
Part	The part whose demand could not be sourced due to material expiry limitations, part source effectivity or multi-level source effectivity. **Referenced table:** Part	Reference	Yes

Table 8.37: DemandException (Mfg) fields

Field name	Description	Data type	Owner
Pool	The pool, if any, associated with the demand(s) that could not be sourced. **Referenced table:** Pool	Reference	
Quantity	The amount of the demand that could not be sourced due to material expiry , part source effectivity, or multi-level source effectivity requirements. This value might be less than any single demand quantity. For example, if there is non-expiring supply available to satisfy part of a given demand then only the unsourceable portion of the demand would be reported in this table. Similarly, this value might be greater than any single demand quantity. For example, if a set of demands for a part existed on the same date and with the same priority, they might be processed together by RapidResponse.	Quantity	
Type	Indicates the cause of the demand exception being reported. Exceptions in this table are generated from either material expiry, part source effectivity, or multi-level sourcing logic. Valid values are: • **Expiry**—the exception was generated because non-expiring supply could not be found or planned for a part's demand. • **MLSSourceEffectivity**—the exception was generated because the date when supply could be planned for a part's demand, based on the planned availability and constraint on its components, is outside of the effective date range for the assembly's part source(s). This type of exception is only applicable to parts configured for multi-level sourcing and where **MultiLevelSearchRule.SourceEffectivityRule** is set to"PlannedAvailableDate". • **SourceEffectivityWindow**—the exception was generated because the demand date (less any safety lead time on the part) fell outside of the effectivity window for all part sources and the part's **SourceRule.DateEffectivityRule** setting was "AdjustedDemandDate". **Note:** This field was added in Version 2016.2, Service Update 4, and updated in Version 2016.2, Service Update 8.	String (Enum)	
Unit	The start unit associated with the demand that could not be sourced. Default value is -1.	Integer	

DependentConsensusForecast table

The **DependentConsensusForecast** table shows the result of exploding consensus forecasts through a planning BOM and hence the dependent demands that would be placed on the assembly's option components. These demands are not used in other planning (for example, they are not reported in CTPForecast or Forecast tables), but rather are intended for comparison against the statistical forecasts generated for the planning BOM components. For example, if the dependent forecast values generated here are significantly different from the component's statistical forecasts, this might indicate issues with the defined planning BOM ratios.

Table 8.38: DependentConsensusForecast (Mfg) fields

Field name	Description	Data type	Owner
BOM	A reference to the bill of material relationship that drove the dependent consensus forecast reported on this record. This table only calculates dependent consensus forecasts from **BillOfMaterial** records that satisfy the following conditions: • **Type.RatioRule** is either "Fraction" or "Percent". • **Assembly.Type.ProcessingRule** is either "MPS", "MPSConfig", or "Ignore". • **Component.Type.ProcessingRule** is "MPS". **Referenced table:** BillOfMaterial	Reference	
Date	The date of this dependent consensus forecast. Based on the original consensus forecast date (**ParentConsensusForecast.Date**) and offset by the lead time for the assembly's primary "Make" source (**ParentPartSource.EffLeadTime**) as well as any applicable lead time offset defined on the bill of material (**BOM.LeadTimeOffset**).	Date	
ParentConsensus Forecast	A reference to the consensus forecast generated for the assembly during the sales and operations planning process that led to the dependent forecast reported on this record. **Referenced table:** ConsensusForecast	Reference	
ParentPartSource	A reference to the primary "Make" part source for the assembly that the original consensus forecast pertains to. Used to retrieve the appropriate lead time values for calculating the dependent forecast date. **Referenced table:** PartSource	Reference	
Part	A reference to the component part that this dependent forecast was generated for. **Referenced table:** Part	Reference	Yes

Table 8.38: DependentConsensusForecast (Mfg) fields

Field name	Description	Data type	Owner
PartCustomer	A reference to the part and customer forecast this dependent forecast pertains to. Set to the record in the **PartCustomer** table that references the component part the dependent forecast is for and customer on the original consensus forecast for the assembly. Null if no such record exists. **Referenced table**: PartCustomer	Reference	
Quantity	The amount of dependent consensus forecast placed on the component. Based on the assembly's original consensus forecast quantity and then adjusted for factors such as quantity per, option ratio, and so on.	Quantity	

DependentDemand table

This is a consolidation table that combines **Allocation**, **NewAllocation** and **PlannedAllocation** tables to form dependent demand. Only records that are processed by netting at the Part are included. Any demand from the part's WhereUsed bills that are blown through will not be included in the dependent demand for this part. It will appear in the dependent demand of a lower part. This table shows the Unconsumed portion as RemainingQuantity if reporting dependent forecast.

Table 8.39: DependentDemand (Mfg) fields

Field name	Description	Data type	Owner
Allocation	Allocation creating this dependent demand. **Referenced table**: Allocation	Reference	
AlternatePart	The part the demand was created for. This value is different from the Part field value only if that part is interchangeable or globally substitutable with this part as follows: • If the part belongs to a set of interchangeable parts, then Part is the primary part and AlternatePart is the part where the demand came from. • If the part belongs to a set of globally substitutable parts, then Part is the part that needed the supply and AlternatePart is the part where the demand came from. **Referenced table**: Part	Reference	
BillOfMaterial	The BillOfMaterial record used to create dependent demand. (Null if from an Allocation.) **Referenced table:** BillOfMaterial	Reference	

Table 8.39: DependentDemand (Mfg) fields

Field name	Description	Data type	Owner
DueDate	The date on which the demand is scheduled to be satisfied.	Date	
EarliestExpiry Date	The earliest date that a supply may expire if it is to be used in satisfying this demand. The calculation of this field depends on the **PartType.ExpiryRule** value found on the assembly/parent part that generated this demand: • If the assembly has a **PartType.ExpiryRule** of "Dependent", then this value is inherited directly from the **EarliestExpiryDate** on the parent supply. • If the assembly has a **PartType.ExpiryRule** of "Self", then this value is calculated starting from the **DueDat**e on this dependent demand record and adding the assembly's **Part.MinimumShelfLife** value (in units of its ExpiryCalendar). • If the assembly has a **PartType.ExpiryRule** of "SelfReset", then this value is calculated starting from the **DueDate** on this dependent demand record and adding the component's **Part.MinimumShelfLife** value (in units of its ExpiryCalendar). **Note:** If the part this demand is for has a **PartType.ExpiryRule** of "Ignore", then this field always returns a value of "Future".	Date	
IsForecast	Valid values are: • Y • N This field is set to 'Y' if the dependent demand has Type.ProcessingRule= 'SalesForecast'.	Boolean	
Inventory Transfer	The inventory transfer creating this dependent demand. **Referenced table:** InventoryTransfer	Reference	
Model	The model used when netting this record. **Referenced table:** Model	Reference	
Part	The part that has the demand. **Referenced table:** Part	Reference	Yes
PegModel	The model that is applicable to this demand. The field is copied from the demand being reported regardless of the value for Part.MUEPoolNettingType.ModelRule. **Referenced table:** Model	Reference	
PegPart	The part that this demand will go into. **Referenced table:** Part	Reference	

Table 8.39: DependentDemand (Mfg) fields

Field name	Description	Data type	Owner
PegPool	The pool that is applicable to this demand. This field is copied from the demand being reported regardless of the value for Part.MUEPoolNettingType.PoolRule. **Referenced table:** Pool	Reference	
PegSource	The source of this dependent demand. Valid values are: • **PlannedAllocation**—the source supply is a planned order, exploded through a BillOfMaterial. PlannedOrder and BillOfMaterial references are valid. • **NewAllocation**—the source supply is a scheduled receipt, exploded through a BillOfMaterial. PegSR and BillOfMaterial references are valid. • **Allocation**—the source supply is an Allocation record for a ScheduledReceipt. Allocation and PegSR references are valid. • **TransferAllocation**—the source supply is a planned Transfer order. PlannedOrder is valid. • **Transfer**—The source supply is a Transfer scheduled receipt. PegSR is valid. • **InventoryTransfer**—the source supply is an inventory transfer. • **Substitute**	String (Enum)	
PegSR	The ScheduledReceipt that creates this dependent requirement (Null if planned). **Referenced table:** ScheduledReceipt	Reference	
PlannedOrder	The planned order that creates this dependent requirement (Null unless planned). **Referenced table:** PlannedOrder	Reference	
Pool	The pool used when netting this record. **Referenced table:** Pool	Reference	
Remaining Quantity	The amount that is still needed. If the Demand is Forecast, this field shows the unconsumed portion of the forecast. This is the sum of UnconsumedQty from Forecast records associated with this dependent forecast.	Quantity	
ReschedDate	The Date MRP moved the DueDate to (may be moved if the supply is rescheduled).	Date	
StartUnit	The start unit that is applicable to this demand. The field is copied from the demand being reported regardless of the value for Part.MUEPoolNettingType.UnitRule.	Integer	

Table 8.39: DependentDemand (Mfg) fields

Field name	Description	Data type	Owner
SubstituteSupply	The substitute supply that created the dependent demand. **Referenced table:** SubstituteSupply	Reference	
TotalQuantity	The amount that was needed. If the Demand is Forecast, TotalQuantity shows the forecast (either dependent or independent) before spreading and consumption.	Quantity	
Type	The type of the supply in which this demand will be used. The demand type can be determined from the SupplyType using the AllocationDemandType field. **Referenced table:** SupplyType	Reference	
Unsatisfied Quantity	The portion of this dependent demand that was left unsatisfied.	Quantity	

DirectAssembly table

The **DirectAssembly** table reports immediate parent assemblies that can potentially use a given component part (and hence might cause dependent demand to be placed on the component). Assembly parts reported for a given component are those ultimately related through standard BillOfMaterial records, co/by-product relationships, global and BOM-level substitute relationships, Allocation records, and transfer PartSource records.

This table was added in Version 2016.2, Service Update 3. If knowledge of indirect assemblies found multiple levels above the component is required, use the **FlatAssembly** table.

Table 8.40: DirectAssembly (Mfg) fields

Field name	Description	Data type	Owner
Assembly	The name of a direct parent assembly that can potentially use the component. **Referenced table:** Part	Reference	
Part	The name of the component part that can potentially be used in the building of the parent assembly. **Referenced table:** Part	Reference	Yes

DirectComponent table

The **DirectComponent** table reports all immediate components parts that can potentially be used directly in a given assembly. This includes components related to the assembly through standard BillOfMaterial records, co/by-product relationships, BOMAlternate records, input Allocation records, and transfer PartSource records.

This table was added in Version 2014.1

Table 8.41: DirectComponent (Mfg) fields

Field name	Description	Data type	Owner
Component	The name of a component that can potentially be used directly in the assembly part. **Note:** Each assembly will have a record identifying itself as its own component. **Referenced table:** Part	Reference	
Part	The name of the assembly part that can directly use the component. **Referenced table:** Part	Reference	Yes

DisaggregationRateByPartCustomer table

The **DisaggregationRateByPartCustomer** table reports general disaggregation rates for part-customer and forecast category combinations.

The rates in this table are typically calculated based on either the default parameters provided in the **SOPAnalyticsConfiguration** table or forecast category specific parameters provided in the **ForecastDisaggregationParametersByCategory** table or part-customer and forecast category specific parameters provided in the **ForecastDisaggregationParameters** table. Additionally, if the **DisaggregationQuantityRule** field on the **HistoricalDemandCategoryType** table is set to "Actuals", the **ForecastDisaggregationOverride** table can be used to specify rates for a particular part-customer and forecast category on specific dates and these will then be reported in the **DisaggregationRateByPartCustomer** table, rather than calculating them for that part-customer and category on that date. If the **DisaggregationQuantityRule** field on the **HistoricalDemandCategoryType** table is set to "ConsensusForecast", the adjustments in **ForecastDisaggregationOverride** table and the **DisaggregationInnerCalendar** and **DisaggregationOuterCalendar** fields on the **SOPAnalyticsConfiguration** table are not used.

Notes:

- If causal quantities are reported in the **CausalFactorDetail** table, they are reflected in this table.
- In order for this table to calculate disaggregation rates for a particular forecast category, the name of a valid **HistoricalDemandCategory** value must be passed to the table using an analytic parameter. For more information, see "Calculate general disaggregation rates by forecast category" on page 2236.

Table 8.42: DisaggregationRateByPartCustomer (Mfg) fields

Field name	Description	Data type	Owner
Category	A reference to the forecast category that the disaggregation rates reported for the part customer on this record pertain to. **Referenced table:** HistoricalDemandCategory	Reference	
Date	The date in the disaggregation calendar, which defines the periods that orders can be disaggregated into.	Quantity	
EffectiveUnitPrice	The unit price used as the rate for disaggregation by revenue. • RapidResponse checks the **CustomerPrice** table for records with matching Part and Customer values that have effective dates less than or equal to the date of this record. If any matching records are found, then the **UnitPrice** from the record with the latest effective date is reported here. Note that if multiple records exist for a given part and customer combination with the same effective date, record with the larger value in the **CustomerPrice.Id** field is used. • However, if no matching **Part** and **Customer** values are found, RapidResponse next check the **CustomerPrice** table for records with a matching **Part** and blank **Customer** value (that is, ' ') that have effective dates less than or equal to the record date. If any matching records are found, then the **UnitPrice** from the record with the latest effective date is reported here. • Finally, if no unit price can be found under any of the conditions mentioned above or if the value provided in **CustomerPrice.UnitPrice** is negative, the value in **Part.AverageSellingPrice** is reported here. However, if the value in **Part.AverageSellingPrice** is also negative, then **DisaggregationRateByPartCustomer.EffectiveUnitPrice** is set to zero. However, if a **PartCustomer** is a component of an aggregate (has aggregates), then no **DisaggregationRateByPartCustomer** records are generated for it. If a **PartCustomer** is an aggregate (has components), then it needs to gather history from itself and all its components. The formula for **EffectiveUnitPrice** gives a weighted average of the components' **EffectiveUnitPrice**. In particular, it maintains the following relation for revenue: Revenue = **Quantity** X **EffectiveUnitPrice**.	Money	

Table 8.42: DisaggregationRateByPartCustomer (Mfg) fields

Field name	Description	Data type	Owner
Header	A reference to the part customer and forecast category combination this set of values applies to. **Referenced table:** HistoricalDemandHeader	Reference	
PartCustomer	A reference to the part and customer combination the disaggregation rate applies to. Note that if records are added to the **AggregatePartCustomer** table, then results are not generated in this table for component **PartCustomer** values (only rates for aggregate **PartCustomer** values as well as **PartCustomer** values that do not belong to aggregate part customer groupings are reported here). **Referenced table:** PartCustomer	Reference	Yes
Quantity	The quantity used as the rate for disaggregation by unit. The quantity is calculated based on historical demand actuals or the consensus forecast, which is determined by the value set in **HistoricalDemandCategoryType.DisaggregationQuantityRule**. If an override quantity is found in **ForecastDisaggregationOverride.Quantity**, it will be reported here.	Quantity	
QuantityWithoutOverride	The default quantity for disaggregation by unit that is calculated based on historical demand actuals or the consensus forecast. If an override quantity is found in **ForecastDisaggretationOverride.Quantity**, it is not reported here. **Note:** This field was added in Version 2016.2, Service Update 15.	Quantity	

EventConsensusForecastDetail table

The **EventConsensusForecastDetail** table is used for Event Management. It holds information about forecast items that have event-based forecast adjustments applied and also belong to forecast categories that are used to generate the consensus forecast. The records in the **EventForecastDetailAdjustment** table are used as a source for the records in this table. For more information, see "Event Management and the RapidResponse data model — calculated tables" on page 2120.

This table is analogous to the **ConsensusForecastDetail** table, which uses the **ForecastDetail** table as a source and reports only the forecast details needed to generate the consensus forecast. Both the **EventConsensusForecastDetail** table and the **ConsensusForecastDetail** table are used to generate the forecast in the **ConsensusForecast** table.

This table was added in Version 2016.2, Service Update 3.

Note: To avoid duplicating information, forecast details that are reported in the **EventConsensusForecastDetail** table are not included in the **ConsensusForecastDetail** table. This means that applying an event phase to the forecast might reduce the number of records in the **ConsensusForecastDetail** table.

Table 8.43: EventConsensusForecastDetail (Mfg) fields

Field name	Description	Data type	Owner
AverageUnit Price	The weighted average of **EffectiveUnitPrice** for **ForecastDetail** records with the given **Header**, for the specified date bucket. This value comes from the corresponding field in the **EventForecastDetailAdjustment** table.	Money	
AverageUnit PriceAdjustment	The calculated event-based unit price adjustment for this forecast item after all event phases that affect it are applied.	Money	
Consensus Forecast	The **ConsensusForecast** record that this record affects. **Referenced table:** ConsensusForecast	Reference	
Date	The date in the Header.PartCustomer.EffectiveDisaggregationCalendar that represents the forecast bucket that this adjustment applies to.	Date	
Effective Quantity	Effective quantity for this forecast item before event-based adjustments.	Quantity	
Effective Quantity Adjustment	The calculated event-based quantity adjustment for this forecast item after all event phases that affect it are applied.	Quantity	
EventForecast Detail Adjustment	The EventForecastDetailAdjustment record from which this record is derived. **Referenced table:** EventForecastDetailAdjustment	Reference	
Header	The HistoricalDemandHeader record that identifies the forecast stream (part, customer, and historical demand category) for which results are shown. **Referenced table:** HistoricalDemandHeader	Reference	
Part	The part that this adjustment applies to. **Referenced table:** Part	Reference	Yes

EventDisaggregationRate table

This table is used for Event Management. It provides visibility into the calculations performed when applying event-based quantity adjustments to the forecast.

To apply quantity adjustments to forecast items, the affected forecast details reported in the **ForecastDetails** table are first bucketed using the calendar specified for the event phase. For example, if the event phase increases the forecast quantity by a certain amount for each month, the forecast details for the affected periods are bucketed using the month calendar. The result is reported in the **EventDisaggregationRate** table. For more information, see "Event Management and the RapidResponse data model — calculated tables" on page 2120.

Records might also be added to the **EventDisaggregationRate** table for forecast items that did not have forecast quantities previous to the event phase being applied.

Forecast items that are only subject to unit price adjustments are not included in the **EventDisaggregationRate** table.

This table was added in Version 2016.2, Service Update 3.

Table 8.44: EventDisaggregationRate (Mfg) fields

Field name	Description	Data type	Owner
Date	The date on the **EventPhase** calendar that begins the forecast bucket that this record applies to.	Date	
EventPhase	The event phase that affects this forecast item **Referenced table:** EventPhase	Reference	Yes
EventPhase Header	The event phase header that connects the **EventPhase** to an **HistoricalDemandHeader** that the event phase applies to. **Referenced table:** EventPhaseHeader	Reference	
Quantity	Bucketed forecast quantity associated with the **Date** and **HistoricalDemandHeader** referenced by **EventPhaseHeader**. The forecast quantity comes from the data in the **ForecastDetail** table. This is the forecast quantity before event-based forecast adjustments.	Quantity	
Weight	Ratio of the **Quantity** on the **Date** among the total of **Quantities** (on this **Date**) for valid **Headers** associated with the **EventPhase**	Quantity	

EventForecastDetailAdjustment table

This table is used for Event Management. It reports the adjustment details, including any quantity or unit price adjustments, for each forecast item that is affected by event-based adjustments. Detail records on this table for forecast items that contribute to the consensus forecast are used to populate

the **EventConsensusForecastDetail** table. For more information, see "Event Management and the RapidResponse data model — calculated tables" on page 2120.

A single record is included on this table for each affected forecast item in each affected **EventPhase.Calendar** bucket, and the results of all event-based forecast adjustments applied to it are calculated. For example, if a forecast item in a given date bucket is affected by an event phase that increases the unit price by $10, an event phase that decreases the quantity by 100, and an event phase that increases the quantity by 50, the value in the **AverageUnitPriceAdjustment** field would be $10, and the value in the **QuantityAdjustment** field would be -50.

This table was added in Version 2016.2, Service Update 3.

Table 8.45: EventForecastDetailAdjustment (Mfg) fields

Field name	Description	Data type	Owner
AverageUnit Price	The weighted average of **EffectiveUnitPrice** for F**orecastDetail** records with the given **Header** and the bucket specified by **Date**. If there are no **ForecastDetail** records in the appropriate period, the value is calculated in the same way as **EffectiveUnitPrice** on the **ForecastDetail** table on the **Date.**	Money	
AverageUnit Price Adjustment	Calculated adjustment to the average unit price.	Money	
Date	The date on the calendar specified in **Header.PartCustomer.EffectiveDisaggregationCalendar** field when the **EffectiveQuantityAdjustment** is applied.	Date	
Effective Quantity Adjustment	The value in the **QuantityAdjustment** field, unless the adjustment would result in a negative forecast amount and **Header.Category.Type.EventAllowNegative** is set to "false." This value is used in subsequent calculations, such as calculating the consensus forecast.	Quantity	
Header	The **HistoricalDemandHeader** record that identifies the part, customer, and historical demand category for which results are calculated. **Referenced table:** HistoricalDemandHeader	Reference	Yes
Original Quantity	Total of **ForecastDetail.Quantity** for records with the given **Header** and the bucket specified by **Date.** If there are no **ForecastDetail** records in the appropriate period, the value is 0.	Quantity	
Quantity Adjustment	The quantity to adjust the forecast by.	Quantity	

EventStatisticalDisaggregationRate table

This table is used for disaggregation of statistical forecast items affected by Event Management. Its results, along with data from other tables, are used to calculate the list of event-based statistical forecast adjustments that appears in the **EventStatisticalForecastDetailAdjustment** table. For more information, see "Reporting statistical forecast adjustments" on page 2123.

To calculate quantity adjustments for statistical forecast items, the affected forecast details reported in the **EventStatisticalForecastDetail** table are first bucketed using the calendar specified for the event phase. For example, if the event phase increases the forecast quantity by a certain amount for each month, the forecast details for the affected periods are re-bucketed using the month calendar.

Records might also be added to the **EventStatisticalDisaggregationRate** table for forecast items that did not have forecast quantities previous to the event phase being applied.

Statistical forecast items that are only subject to unit price adjustments are not included in the **EventStatisticalDisaggregationRate** table.

This table is analogous to the **EventDisaggregationRate** table, which is based on the records in the **ForecastDetails** table and reports results for other forecast categories in addition to the statistical forecast.

This table was added in Version 2016.2, Service Update 3.

Table 8.46: EventStatisticalDisaggregationRate (Mfg) Fields

Field name	Description	Data type	Owner
Date	The date on the **EventPhase** calendar that begins the forecast bucket that this record applies to.	Date	
EventPhase	The event phase that affects this forecast item. **Referenced table:** EventPhase	Reference	Yes
EventPhase Header	The event phase header that connects the **EventPhase** to an **HistoricalDemandHeader** that the event phase applies to. **Referenced table:** EventPhaseHeader	Reference	
Quantity	Bucketed forecast quantity associated with the **Date** and **HistoricalDemandHeader** referenced by **EventPhaseHeader**. The forecast quantity comes from the data in the **EventStatisticalForecastDetail** table. This is the forecast quantity before event-based forecast adjustments. If there are no **EventStatistical ForecastDetail** records in the appropriate period, the value is 0.	Quantity	
Weight	Ratio of the **Quantity** on the **Date** among the total of **Quantities** (on this **Date**) for valid **Headers** associated with the **EventPhase**	Quantity	

EventStatisticalForecastDetail table

This table is used for Event Management. It contains information about statistical forecast items that are affected by event phases. Its results, along with data from other tables, are used to calculate the event-based statistical forecast adjustments listed in the **EventStatisticalForecastDetailAdjustment**table. For more information, see "Reporting statistical forecast adjustments" on page 2123.

This table was added in Version 2016.2, Service Update 3.

Table 8.47: EventStatisticalForecastDetail (Mfg) fields

Field name	Description	Data type	Owner
Date	Date representing the forecast bucket. This date belongs to Header.PartCustomer.EffectiveDisaggregationCalendar.	Date	
Header	The HistoricalDemandHeader associated with the statistical forecast data. **Referenced table:** HistoricalDemandHeader	Reference	
ItemParameters	Reference to the ForecastItemParameters record associated with this forecast item. **Referenced table:** ForecastItemParameters	Reference	Yes
Quantity	Forecast quantity associated with the **Date** and **Header.**	Quantity	

EventStatisticalForecastDetailAdjustment table
