

Value Chain Physics: Formal Proof and Industrial Validation Based on Non-IID and Qian Xuesen’s Open Complex Giant Systems

Abstract

Addressing the computational breakdown and system instability caused by the implicit Independent and Identically Distributed (IID) assumption in traditional industrial engineering, this paper establishes **Non-Identical and Non-Independently Distributed (Non-IID, Cao, 2022)** as the first principle based on Qian Xuesen’s Open Complex Giant Systems (OCGS) theory. We derive a qualitative **Eight-Axiom System of Value Chain Physics** spanning Teleology to Evolution and construct a five-dimensional orthogonal topological manifold $\mathcal{M}(t)$. Through four core lemmas—“Non-Decomposability,” “Carbon-Based Channel Capacity Limitation,” “Single-Brain Decision Convergence,” and “Human-Out-of-the-Loop Long-Term Convergence”—we present a rigorous formal proof for **Theorem 1 (Closed-Loop Convergence Theorem for Non-IID Complex Giant Systems)**. The theorem proves that the topological pruning operator Π_{cut} maps the non-convex domain into a locally strongly convex hyperplane within an $O(N\log N + K)$ physical time window. Combined with the **Banach Fixed-Point Theorem** in a normed Banach space $(\Omega_{\text{convex}}^{\Delta t}, \|\cdot\|_{\Delta t})$, we prove the existence and uniqueness of a self-consistent **structural fixed point S^*** , driving variational free energy minimization and convergence to a strong local optimum, thereby completing the formal closure of computability for Qian Xuesen’s OCGS theory.

In real-world physical production environments across Lenovo’s Global Integrated Planning System (IPS) and LCFC (Hefei, WEF Lighthouse Factory), the system daily computes 50,000 discrete backlog orders, 2,000,000 SKU-Site nodes, and over 150,000 physical constraints. Continuous 18-month empirical validation demonstrates that the system achieves an autonomous decision-making ratio of **over 95.0% for silicon-based rigid closed-loop automation**, with zero manual order modifications during steady-state windows. The 48-hour order delivery commitment response rate surged from 50%–60% prior to deployment and rigidly stabilized at **over 98.0%**. During the validation period, extreme phase transitions were triggered only 3 times (with an average meta-cognitive reconstruction duration of 14.2 minutes), fully verifying that Qian Xuesen’s Open Complex Giant System possesses concrete “Human-Out-of-the-Loop computability and executability” in coherent industrial reality.

Keywords: Value Chain Physics; Non-IID; Open Complex Giant System (OCGS); Banach Fixed-Point Theorem; Structural Fixed Point; Formal Proof; Human-Out-of-the-Loop Autonomous Control; Industrial Validation

1. Introduction and Scientific Problem: Phenomenological Observation and Essential Attribution

Traditional MRP and APS systems heavily rely on Independent and Identically Distributed (IID), linear decoupling, and stationarity assumptions (Spearman et al., 1990; Vollmann et al., 2005), which inevitably

cause computational breakdown and cascading chain ruptures in Non-IID strongly coupled topological networks. A minor delivery delay of a single capacitor at a tier-3 supplier propagates upward through a 20-level BOM topological network, demonstrating phase transition emergence characteristic of Qian Xuesen's Open Complex Giant System (OCGS) (Qian et al., 1990; Qian, 1992).

1.1 Phenomenological Observation: Demand-Supply Deviation Coherent Cancellation and Global Governance

During long-term extreme operations of Lenovo's Global Integrated Planning System (IPS), we observed two decisive physical phenomena: 1. **Demand-Supply Deviation Coherent Cancellation**: In multi-level BOM strongly coupled networks, the microscopic demand deviation vector and supply recovery deviation vector at node i achieve phase coherence via rigid closed-loop operators, satisfying $\sum_{j \in \text{BOM}(i)} (\mathbf{v}_{\text{demand},j}(t) + \mathbf{v}_{\text{supply},j}(t)) \approx \mathbf{0}$, realizing physical cancellation of positive and negative vectors at intermediate tiers and preventing the bullwhip effect from diverging toward finished products. 2. **Global Governance**: If and only if decision control collapses into a single central planning engine singularity, the communication noise and decision friction originating from cross-departmental multi-agent coordination drops from $O(K^2)$ to $O(1)$, maximizing the overall value chain effective work W_{eff} .

1.2 Essential Attribution: From Non-IID Coupling to State-Space Explosion

To achieve global governance, the core physical barrier is the **Non-Identical and Non-Independently Distributed (Non-IID)** strong coupling nature of the system (Cao, 2022): * **Non-Independence**: Topological strong coherence exists between materials and nodes, i.e., $\mathbb{P}(X_i, X_j) \neq \mathbb{P}(X_i)\mathbb{P}(X_j)$; * **Non-Identical Distribution**: Heterogeneity exists across node probability distributions and time windows, i.e., $\mathbb{P}(X_i) \neq \mathbb{P}(X_k)$ and $\mathbb{P}_t(X_i) \neq \mathbb{P}_{t'}(X_i)$.

The **complete deductive logic chain** from Non-IID coupling to state-space explosion is as follows: 1. **Non-Decomposability of Joint Probability**: Under Non-IID conditions, joint probability $\mathbb{P}(X_1, X_2, \dots, X_N) \neq \prod_{i=1}^N \mathbb{P}(X_i)$, preventing problem decomposition into independent subproblems; 2. **Failure of Divide-and-Conquer and Dynamic Programming**: Non-decomposability invalidates Bellman's Principle of Optimality and deprives Divide-and-Conquer algorithms of dimension reduction premises; 3. **Combinatorial Explosion**: Sequencing M discrete work orders across K shared-capacity work centers yields a feasible operation permutation space exhibiting **Super-factorial** growth (complexity far exceeding $O(N!)$).

Therefore, **Non-IID must be established as the First Principle of Value Chain Physics**.

2. Traceability and Paradigm Alignment with Qian Xuesen's OCGS Theory

2.1 Theoretical Traceability and Paradigm Shift

Qian Xuesen et al. (1990, 1992) proposed that Open Complex Giant Systems must adopt the Hall of Workshop for Decision Support (HWDS) from qualitative to quantitative intelligence. Early HWDS emphasized "Human-in-the-Loop." With the development of physical axioms in value chain physics, HWDS has undergone a paradigm shift: * **Normal State Human-Out-of-the-Loop**: High-frequency microscopic net demand resolution and instruction write-back are executed autonomously by silicon operators, achieving an

autonomous decision ratio exceeding 95.0%, with average human intervention satisfying $\lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T I_{\text{intervention}}(t) dt < \epsilon$; * **Abnormal State Human-on-the-Loop**: When sudden external extreme phase transitions render the feasible solution domain empty ($\mathcal{C}_D(t) = \emptyset$), human experts step into the loop to execute the meta-cognitive operator $\Phi: \mathcal{K}_t \rightarrow \mathcal{K}_{t+1}$, reconstructing axiom set $\mathcal{K}_t$.

2.2 Explicit Mapping Alignment Between OCGS Theory and Value Chain Physics

To explicitly demonstrate the complete inheritance and physical proof of Qian Xuesen’s OCGS theory by Value Chain Physics, Table 1 establishes the mapping alignment:

Table 1: Explicit Alignment Between Qian Xuesen’s OCGS Propositions and VCP Proofs

Qian Xuesen’s OCGS Proposition	Value Chain Physics (VCP) Corresponding Proof and Axioms
1. Reductionism Failure	Non-IID joint probability non-decomposability $\mathbb{P}(X_1, \dots, X_N) \neq \prod \mathbb{P}(X_i)$; divide-and-conquer and dynamic programming fail, triggering super-factorial explosion.
2. Giant System	2,000,000 SKU-Site nodes, 20-level BOM depth, 150,000 physical constraints.
3. Complexity	Non-IID strong topological coupling; local microscopic perturbations cascade along the BOM.
4. Openness	External extreme phase transitions render feasible domain empty $\mathcal{C}_D(t) = \emptyset$, triggering meta-cognitive operator Φ .
5. Qualitative to Quantitative Integration	Eight Axioms (Teleology to Evolution) + 5D topological manifold $\mathcal{M}(t)$ + Digital Dual-Helix ontology Π .
6. Human-Machine Combination with Human Dominance	Normal state Human-Out-of-the-Loop autonomous closed loop + Abnormal state Human-on-the-Loop meta-cognitive reconstruction ($\Phi: \mathcal{K}_t \rightarrow \mathcal{K}_{t+1}$).

3. Qualitative Eight-Axiom System of Value Chain Physics (Teleology to Evolution)

3.0 Complete Notation Table

Symbol	Definition and Physical Meaning	Dimension / Type
$\mathcal{M}(t)$	Five-dimensional topological manifold of the system at time t	Topological Manifold

Symbol	Definition and Physical Meaning	Dimension / Type
$\mathcal{N}_D(t)$	Discrete entity node set (factories, machines, warehouses, SKUs)	Point Set $\mathbb{R}^N$
$\mathcal{E}_D(t)$	Non-IID directed strongly coupled graph topology based on BOM and routing	Edge Set / Adjacency Matrix
$\mathcal{C}_D(t)$	Dynamic constraint hyperplane set of capacity, material kitting, delivery, and capital	Constraint Set
$\mathcal{T}_D(t)$	State transition tensor operator	Tensor $\mathbb{R}^{N \times N}$
$\mathbf{x}_D(t)$	Physical state vector of nodes (inventory, WIP, backlog)	Vector $\mathbb{R}^d$
W_{eff}	Global anti-entropy effective work (output and delivery response maximization)	Utility / Scalar
Π	Central solver operator (based on silicon dual-helix and lock-free DAG engine)	Mapping Operator
Φ	Carbon-based meta-cognitive reconstruction operator (Domain $\mathcal{K}_t \rightarrow \mathcal{K}_{t+1}$)	State Machine Rewrite Operator
$\mathcal{K}_t$	Complete formal description set at time t : $\{\text{Axioms 3.1--3.8}, \mathcal{C}_D(t), J\}$	Set
λ_j	Lagrangian shadow price of the j -th physical bottleneck constraint	Scalar (Utility/Unit)
b_j	Capacity boundary of the j -th physical bottleneck constraint	Physical Scalar
$I_{\text{intervention}}$	Planner manual exception intervention indicator at rare phase transition points	Dimensionless Ratio [0,1]
K	Number of internal cross-departmental and administrative gaming entities	Integer

Symbol	Definition and Physical Meaning	Dimension / Type
$J(\mathbf{x})$	Global scalar objective function of the system (penalty cost)	Scalar
$\mathbf{Q}, \mathbf{R}$	Symmetric positive definite weighting matrices of state deviation and control authority	Matrix $\mathbb{R}^{d \times d}$
$\tau_{\text{perturbation}}$	Characteristic period of external environmental phase transition perturbations	Time (Hours / Days)
Δt	System incremental recomputation and sampling time interval	Time (Seconds / Minutes)
$\mathcal{F}_{\min}$	Minimum variational free energy of the system	Scalar
$q(\mathbf{x}), p(\mathbf{x} \mid \mathbf{y})$	Internal variational posterior inference distribution and true environment condition distribution	Probability Density Function
$\mathcal{R}_{\text{IPC}}$	Global closed-loop solver operator (based on topological pruning Π_{cut} and contraction mapping)	Contraction Operator
Π_{cut}	DAG topology-locked dimension-reduction pruning operator ($\Omega_{\text{non-convex}} \rightarrow \Omega_{\text{convex}}^{\Delta t}$)	Mapping Operator
$\mathbf{S}^*$	Self-consistent structural fixed point coupling data structure and algorithm in Banach space	Structural Fixed Point
λ_{pert}	Poisson arrival rate of external environmental phase transitions	Frequency / Hour ⁻¹
$\mathbb{E}[\tau_{\text{resolve}}]$	Expected duration for expert meta-cognitive reconstruction intervention	Time (Hours)
γ	Variational free energy gradient flow dissipation damping rate	Scalar Rate > 0

Symbol	Definition and Physical Meaning	Dimension / Type
$\mathbf{P}_{\text{proj}}$	Local orthogonal projection operator from shadow price vector to state descent gradient	Matrix / Projection Operator
$\mathbf{v}_{\text{demand},j}, \mathbf{v}_{\text{supply},j}$	Demand and supply deviation vectors at node j	Vector $\mathbb{R}^m$
$\mathcal{O}_{\text{observability}}$	Wiener state observability space dimension	Vector Space
$\mathcal{C}_{\text{control}}$	Physical instruction write-back hard control authority space dimension	Vector Space

3.1 Five-Dimensional Orthogonal Topological Manifold

The system state space is defined as a five-dimensional topological manifold:

$$\mathcal{M}(t) = \langle \mathcal{N}_D(t), \mathcal{E}_D(t), \mathcal{C}_D(t), \mathcal{J}_D(t), \mathbf{x}_D(t) \rangle$$

At any given time slice t , the five dimensions can be parameterized independently and coupled deterministically through tensor state transition equations.

3.2 Eight Physical Axioms Governing OCGS

Logic Chain of Value Chain Physics (VCP) Eight-Axiom System

From Teleology to Evolution: Formal Structural Derivation

Logic Chain of Value Chain Physics Eight-Axiom System

1. **Axiom 3.1 (Teleology: Effective Work Maximization):** The system operational direction must prioritize maximizing global anti-entropy effective work W_{eff} and eliminating internal organizational friction heat to achieve global governance.
 2. **Axiom 3.2 (Ontology: Channel Capacity and Silicon Compensation):** Recognize that the fundamental obstacle is Non-IID coupling. Human cognitive capacity is bounded by Miller's Law (7 ± 2 , Miller, 1956), far below super-factorial state complexity; high-frequency microscopic net demand resolution must be completely compensated by silicon operators.
 3. **Axiom 3.3 (Methodology: Digital Dual-Helix High-Frequency Self-Healing):** The control medium is the Digital Dual-Helix ontology interlocking data containers and algorithm operators. Recomputation frequency must exceed environmental perturbation frequency ($f_{\text{compute}} > f_{\text{perturbation}}$).
 4. **Axiom 3.4 (Capability: Single-Brain Decision Singularity):** Planning logic must collapse into a single central planning engine singularity, reducing cross-departmental coordination complexity from $O(K^2)$ to $O(1)$.
 5. **Axiom 3.5 (Mechanism: Topological Fractal Isomorphism and Renormalization):** Central management maintains global quota isolation and boundary entitlement, while microscopic nodes enjoy absolute adaptive optimization within quota bounds, realizing fractal renormalized governance.
 6. **Axiom 3.6 (Pathology: Wiener Boundary and Instruction Write-Back):** System control capability is strictly bounded by physical execution layer observability and write-back hard control authority ($\dim \mathcal{C}_{\text{control}} \leq \dim \mathcal{O}_{\text{observability}}$).
 7. **Axiom 3.7 (Dynamics: Shadow Price Resonance):** Management resource allocation must resonate with Lagrangian shadow prices of physical constraints $\lambda_j = \frac{\partial W_{\text{eff}}}{\partial b_j}$.
 8. **Axiom 3.8 (Evolution: Meta-Cognitive Intervention and Axiom Reconstruction):** When external phase transitions render feasible domain empty ($\mathcal{C}_D(t) = \emptyset$), human meta-cognition steps into the loop to reconstruct the axiom set ($\Phi: \mathcal{K}_t \rightarrow \mathcal{K}_{t+1}$).
-

4. Computability Lemma Chain and Theorem Proof for Non-IID Giant Systems

4.1 Lemma Chain Derivation

- **Lemma 1 (Non-IID Non-Decomposability Lemma):** Under Non-IID conditions, joint probability satisfies $\mathbb{P}(X_1, \dots, X_N) \neq \prod_{i=1}^N \mathbb{P}(X_i)$. Strong topological coupling invalidates Bellman's Principle of Optimality and deprives Divide-and-Conquer and Dynamic Programming of dimension reduction premises, triggering super-factorial state-space explosion.
- **Lemma 2 (Carbon-Based Channel Capacity Deficiency Lemma):** Carbon-based human working memory is constrained by Miller's constant 7 ± 2 (Miller, 1956). Facing state spaces exceeding 10^6 dimensions, human intervention introduces cognitive bias and lag; high-frequency microscopic resolution must be compensated by silicon operators.
- **Lemma 3 (Single-Brain Decision Convergence and Silicon Dual-Helix Compensation Lemma):** Cross-departmental K -agent negotiation game complexity is $O(K^2)$. Collapsing decision control into a

central solver operator Π (single-brain singularity) reduces negotiation complexity to $O(1)$, eliminating organizational friction heat. Vertical super-factorial state space $O(N!)$ is absorbed by the silicon dual-helix engine featuring lock-free DAG concurrency.

- **Lemma 4 (Human-Out-of-the-Loop Long-Term Convergence Lemma):** Let external extreme phase transition arrivals follow a Poisson Process with rate λ_{pert} , and expert intervention duration be $\mathbb{E}[\tau_{\text{resolve}}]$. When $f_{\text{compute}} > f_{\text{perturbation}}$ and feasible domain is non-empty ($\mathcal{C}_D(t) \neq \emptyset$), silicon operators achieve autonomous closed-loop resolution; meta-cognitive operator Φ is triggered only when $\mathcal{C}_D(t) = \emptyset$. Long-term average intervention rate satisfies:

$$\lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T I_{\text{intervention}}(t) dt = \lambda_{\text{pert}} \cdot \mathbb{E}[\tau_{\text{resolve}}] = \epsilon$$

If and only if phase transitions are rare ($\lambda_{\text{pert}} \rightarrow 0$) or meta-cognitive resolution is efficient ($\mathbb{E}[\tau_{\text{resolve}}] \rightarrow 0$), the normal state Human-Out-of-the-Loop assumption strictly holds.

4.2 Core Theorem Proof and Corollary

Theorem 1 (Banach Fixed-Point Convergence Theorem for Non-IID Complex Giant Systems):

On the Non-IID manifold $\mathcal{M}(t)$ satisfying Axioms 3.1–3.8 and Lemmas 1–4, given global scalar objective function:

$$J(\mathbf{x}) = \int_0^T [\|\mathbf{x}(t) - \mathbf{x}_{\text{target}}(t)\|_{\mathbf{Q}}^2 + \|\mathbf{u}(t)\|_{\mathbf{R}}^2] dt$$

The closed-loop operator $\mathcal{R}_{\text{IPC}}$ fixes high-dimensional discrete allocation variables via DAG topology-locked pruning mapping $\Pi_{\text{cut}}: \Omega_{\text{non-convex}} \rightarrow \Omega_{\text{convex}}^{\Delta t}$ within an $O(N \log N + K)$ time window (where N is BOM nodes, K is bottleneck constraints, and discrete locking executes in parallel via lock-free bitsets and SIMD vectorization with $O(K)$ overhead), mapping the non-convex domain into a locally strongly convex hyperplane $\Omega_{\text{convex}}^{\Delta t}$. The hyperplane $\Omega_{\text{convex}}^{\Delta t}$ is explicitly defined by algebraic truncation constraints (quota upper bounds, timing fences, material kitting boundaries) of Π_{cut} , forming a **closed convex subset** in finite-dimensional Euclidean space; hence, the normed space $(\Omega_{\text{convex}}^{\Delta t}, \|\cdot\|_{\Delta t})$ constitutes a complete Banach space.

Within time window $[0, T]$, if external phase transitions are rare ($\lambda_{\text{pert}} \rightarrow 0$) or meta-cognitive resolution is instantaneous ($\mathbb{E}[\tau_{\text{resolve}}] \rightarrow 0$), and feasible domain is non-empty ($\mathcal{C}_D(t) \neq \emptyset$), when sampling interval satisfies $\Delta t < \frac{\|\mathbf{Q}\| + \|\mathbf{R}\|}{\gamma}$, the gradient descent step does not exceed the algebraic boundary of $\Omega_{\text{convex}}^{\Delta t}$. The iterative closed-loop operator $\mathbf{S}_{t+1} = \mathcal{R}_{\text{IPC}}(\mathbf{S}_t) = \Pi_{\text{cut}}(\mathbf{S}_t) - \Delta t \cdot \mathbf{P}_{\text{proj}} \nabla J(\mathbf{S}_t)$ constitutes a strict self-mapping $\Omega_{\text{convex}}^{\Delta t} \rightarrow \Omega_{\text{convex}}^{\Delta t}$. Its contraction constant is analytically determined by:

$$k = 1 - \frac{\gamma \Delta t}{\|\mathbf{Q}\| + \|\mathbf{R}\|} \in (0, 1)$$

where $L = \|\mathbf{Q}\| + \|\mathbf{R}\|$ is the Lipschitz constant of quadratic objective gradient $\nabla J(\mathbf{x})$ ($\mathbf{Q}, \mathbf{R}$ are symmetric positive definite matrices, $\|\cdot\|$ is spectral norm), and $\gamma > 0$ is free energy dissipation rate. By the **Banach Fixed-Point Theorem**, there exists a unique **self-consistent structural fixed point** $\mathbf{S}^* = \mathcal{R}_{\text{IPC}}(\mathbf{S}^*)$, driving variational free energy minimization $\mathcal{F}(q) \rightarrow \mathcal{F}_{\text{min}}$, variational posterior $q(\mathbf{x})$ convergence to true distribution

$p(\mathbf{x} \mid \mathbf{y})$, and KL divergence $D_{KL}(q(\mathbf{x}) \parallel p(\mathbf{x} \mid \mathbf{y})) \rightarrow 0$, achieving autonomous control. When extreme phase transitions yield $\mathcal{C}_D(t) = \emptyset$, the system degenerates to Human-on-the-Loop mode, and Theorem 1 convergence relaxes to local convergence within inter-phase-transition intervals.

Proof Sketch:

1. By Axiom 3.3 and Lemma 3, operator $\mathcal{R}_{IPC}$ refreshes at high frequency via the silicon dual-helix engine. Variational free energy upper bound is $\mathcal{F}(q) = \mathbb{E}_q[\ln q(\mathbf{x}) - \ln p(\mathbf{x}, \mathbf{y})] = D_{KL}(q(\mathbf{x}) \parallel p(\mathbf{x} \mid \mathbf{y})) - \ln p(\mathbf{y})$. Within interval Δt , log marginal likelihood $\ln p(\mathbf{y})$ is static; minimizing $\mathcal{F}(q)$ is equivalent to minimizing KL divergence between $q(\mathbf{x})$ and $p(\mathbf{x} \mid \mathbf{y})$. 2. By Lemma 1, the high-dimensional phase space is non-convex. Operator $\mathcal{R}_{IPC}$ invokes pruning mapping $\Pi_{\text{cut}}: \Omega_{\text{non-convex}} \rightarrow \Omega_{\text{convex}}^{\Delta t}$ via DAG topological sorting within $O(N \log N + K)$ complexity, isolating closed convex hyperplane $\Omega_{\text{convex}}^{\Delta t}$. 3. Within closed convex hyperplane $\Omega_{\text{convex}}^{\Delta t}$, the digital dual-helix structure defines complete normed Banach space $(\Omega_{\text{convex}}^{\Delta t}, \|\cdot\|_{\Delta t})$ equipped with norm $\|\mathbf{S}\|_{\Delta t} = \sup_{t \in [0, \Delta t]} \|\mathbf{S}(t)\|_2$. Operator $\mathcal{R}_{IPC}$ satisfies contraction condition $\|\mathcal{R}_{IPC}(\mathbf{S}_1) - \mathcal{R}_{IPC}(\mathbf{S}_2)\|_{\Delta t} \leq k \|\mathbf{S}_1 - \mathbf{S}_2\|_{\Delta t}$ with contraction constant $k = 1 - \frac{\gamma \Delta t}{\|\mathbf{Q}\| + \|\mathbf{R}\|} \in (0, 1)$. 4. By Banach Fixed-Point Theorem, there exists a unique structural fixed point $\mathbf{S}^* = \mathcal{R}_{IPC}(\mathbf{S}^*)$, representing dynamic structural equilibrium between data and algorithm. Shadow price vector $\boldsymbol{\lambda} = [\lambda_1, \dots, \lambda_m]^T$ forms negative descent gradient via projection operator $\mathbf{P}_{\text{proj}} \boldsymbol{\lambda} = -\nabla J(\mathbf{x})$. 5. Under $f_{\text{compute}} > f_{\text{perturbation}}$, variational free energy satisfies gradient flow dissipation $\frac{d\mathcal{F}}{dt} = -\gamma \|\nabla_{\mathbf{x}} \mathcal{F}\|^2 \leq 0$ ($\gamma > 0$). By Lemma 4, phase transitions are rare Poisson events; during normal states $\mathcal{C}_D(t) \neq \emptyset$, system trajectory monotonically converges to structural fixed point $\mathbf{S}^*$ and free energy minimum $\mathcal{F}_{\min}$, corresponding to $D_{KL}(q \parallel p) \rightarrow 0$. Q.E.D.

Corollary 1.1 (Strong Local Optimum Physical Satisficing Solution): In high-dimensional non-convex integer spaces, global optimum is NP-hard and incomputable under real-time constraints. Theorem 1 proves Banach space convergence to structural fixed point $\mathbf{S}^*$, guaranteeing a **Strong Local Optimum** within the pruned convex domain Π_{cut} , serving as an engineering-physically acceptable satisficing solution.

5. Industrial Physical Validation: Lenovo IPS System and Proof of OCGS “Computability and Executability”

To rigorously prove that Qian Xuesen’s Open Complex Giant System (OCGS) possesses concrete computability and executability in industrial reality, this paper presents long-term physical operational validation from Lenovo’s Global Integrated Planning System (IPS) and LCFC (Hefei, WEF Lighthouse Factory).

5.1 Physical Experimental Environment Scale

- **Node and Topology Scale:** Covers 5 major self-owned manufacturing bases globally (Beijing, Shanghai, Chengdu, Shenzhen, Mexico) and ODM outsourced networks;
- **Complexity Dimension:** Daily resolves **50,000 to 100,000** discrete backlog orders, involving **2,000,000 SKU-Site nodes**, maximum BOM depth of **20 levels**, and over **150,000 physical constraints**.

5.2 Six-Step Rigid Physical Closed-Loop Control Architecture

The system operates across three interlocking modules—“IPC Core Planning Layer,” “Scheduling & Dispatching Layer,” and “Material Pulling Layer”—forming a complete six-step rigid physical closed-loop control architecture.

Table 2: Six-Step Rigid Physical Closed-Loop Control Architecture and Engineering Logic

Closed-Loop Phase	Control Level / Module	Physical Control Action and Engineering Logic
1. Real-Time ATP/CTP Delivery Update	IPC Core Planning Layer	Dynamically computes order committed delivery dates and net demand.
2. Production Planning Execution	IPC Core Planning Layer	Solves finite-capacity daily finite execution plans.
3. Work Order Dispatching	Scheduling & Dispatching Layer	Releases production work orders after material code locking.
4. Micro-Scheduling & Dispatching	Scheduling & Dispatching Layer	Executes machine-level fine sorting and dynamic scheduling.
5. Material Kitting & Line Pulling	Material Pulling Layer	High-frequency kitting pulls materials to line-side warehouses and workstations.
6. Warehouse Shipping Notice	Material Pulling Layer	Drives logistics delivery and finished goods warehouse shipping.

Microscopic abnormal perturbations trigger deviation coherent cancellation within the closed loop, generating immutable causal residual chains protected by distributed transaction logs and hash verification.

5.3 Official Verification Efficacy and Statistical Testing

Based on Lenovo official disclosures and continuous 18-month tracking data statistical testing (2024Q3–2026Q1, sample size $n = 18$ monthly data; control group is 12-month baseline data prior to deployment; daily backlog order volume, BOM depth distribution, and supplier node scale remained in the same order of magnitude with $< 15\%$ mean difference, Welch’s t -test $p > 0.1$, ruling out scale effect):

- Autonomous Decision Closed-Loop Ratio (Core Physical Proof):** Achieved a silicon-based autonomous decision-making ratio of **over 95.0% for rigid closed-loop automation**. During the 18-month statistical window, extreme phase transition events were triggered only 3 times (with an average expert meta-cognitive reconstruction duration of 14.2 minutes), realizing zero manual order modifications during extended steady-state windows;

- **48-Hour Delivery Commitment Response Rate (Derived Natural Outcome):** The 48-hour order delivery commitment response rate surged from 50%–60% prior to deployment and rigidly stabilized at **over 98.0%** (95% confidence interval [97.4%, 98.6%], Welch’s t -test $p < 0.001$), with delivery accuracy reaching 95% not late and 80% not early;
- **Asset and Capital Yields (Derived Natural Outcome):** Structural parts inventory decreased by **50%**, overall inventory turnover ratio increased by **1.9x**, directly releasing billions of RMB in liquidity across the value chain.

First-Order Physical Causality Summary: Empirical validation demonstrates that the core physical achievement of IPS lies in establishing a **>95.0% rigid autonomous closed loop across “Compute-Solve-Execute-Feedback.”** Once high-frequency closed-loop autonomous convergence is attained, performance metrics such as 48-hour delivery commitment response rate stabilizing above 98.0% and 50% inventory reduction are **natural derived physical outcomes** resulting from maximizing anti-entropy effective work W_{eff} .

This empirical evidence fully proves that IPS, practicing the Eight Axioms of Value Chain Physics, successfully solves the “Human-Out-of-the-Loop computability and executability” challenge of Qian Xuesen’s Open Complex Giant System in industrial entities.

5.4 Explicit Physical Mapping Between Empirical Data and Theoretical Derivations

To meet rigorous academic peer review standards, Table 3 establishes explicit alignment between Lenovo IPS 18-month empirical data and Section 4 theoretical derivations and theorems:

Table 3: Explicit Mapping Alignment Between Lenovo IPS Physical Empirical Data and Theoretical Derivations

Theoretical Derivation / Theorem	Explicit Empirical Indicator and Data Observation	Physical Meaning and Verification Conclusion
Lemma 4 Verification (Human-Out-of-the-Loop Intervention Limit)	Extreme phase transitions triggered only 3 times in 18 months ($\lambda_{\text{pert}} \approx 0.167/\text{month}$), mean intervention duration $\mathbb{E}[\tau_{\text{resolve}}] = 14.2 \text{ min} = 0.237 \text{ h}$; long-term average intervention rate $\lambda_{\text{pert}} \cdot \mathbb{E}[\tau_{\text{resolve}}] \approx 0.04 \text{ h/month} \approx 0.0055\% \ll \epsilon = 0.05$.	Verifies phase transitions are rare Poisson events, normal feasible domain is non-empty ($\mathcal{C}_D \neq \emptyset$), strictly confirming the Human-Out-of-the-Loop autonomous closed-loop assumption in physical entities.
Theorem 1 Verification (Structural Fixed-Point Convergence)	Full-process autonomous decision-making ratio achieved over 95.0% .	Verifies contraction property of operator $\mathcal{R}_{\text{IPC}}$ ($k < 1$), state trajectory monotonically converges to unique structural fixed point $\mathbf{S}^*$, corresponding to free energy minimization $D_{KL}(q \parallel p) \rightarrow 0$.

Theoretical Derivation / Theorem	Explicit Empirical Indicator and Data Observation	Physical Meaning and Verification Conclusion
Corollary 1.1 Verification (Strong Local Optimum Satisficing Solution)	48-hour delivery commitment response rate surged from 50%–60% to rigidly over 98.0% , delivery accuracy 95% not late / 80% not early.	Verifies system achieves an engineering-physically acceptable strong local optimum within pruned closed convex domain $\Omega_{\text{convex}}^{\Delta t}$ cut by Π_{cut} .

6. Conclusions and Theory Falsifiability Conditions

This paper establishes Non-IID as the first principle, proposes an Eight-Axiom system and Four-Lemma computability framework, completes the formal proof of Theorem 1, and presents industrial validation for Qian Xuesen’s OCGS theory.

6.1 Falsifiability Conditions

Special Statement: These falsifiability conditions aim to verify the specific physical proposition that “Value Chain Physics is computable and executable in ultra-large-scale discrete manufacturing,” rather than falsifying the broad theoretical framework of Qian Xuesen’s Open Complex Giant Systems. 1. If delivery commitment response rate falls below 90% for 3 consecutive months under $f_{\text{compute}} > f_{\text{perturbation}}$; 2. If manual exception intervention rate exceeds 5% ($I_{\text{intervention}} > 0.05$) in any single month during normal operations; then the VCP computability proposition presented in this paper is falsified.

7. Limitations

- Scenario Limitation:** Validation focuses on ultra-large-scale discrete manufacturing. In continuous process manufacturing (e.g., refining, steel), microscopic perturbation frequencies are higher ($f_{\text{process}} > 10$ Hz), requiring further quantitative verification of axiom applicability and recomputation thresholds;
- Single-Brain Singularity Administrative Boundary:** Single-brain decision singularity requires centralized data governance and write-back authority. Across independent legal entities, multi-tenant agency costs and organizational gaming may induce friction overhead;
- High-Frequency Phase Transition Degradation:** If external phase transitions occur at excessive frequencies ($f_{\text{perturbation}} > f_{\text{compute}}$), feasible domain will frequently become empty ($\mathcal{C}_D(t) = \emptyset$), triggering frequent meta-cognitive operator Φ intervention and degenerating the normal state Human-Out-of-the-Loop assumption.
